Hepatocellular carcinoma (HCC) is the most common primary liver cancer with a high mortality rate due to limited treatment options. Systemic drug treatments increase patient survival and often extend life by several months. The development of new small molecule chemotherapeutics is both time consuming and costly. Therefore, drug repurposing is being used as an effective strategy to identify and implement new treatment options for this mortal disease. The aim of this study is to identify potential drug candidates for the treatment of HCC through reuse of existing compounds using the machine learning tool MDDeePred. The open target platform, UniProt, ChEMBL, and ExPasy databases were used to create a dataset for MDDeePred to predict drug-target interactions (DTIs). Enrichment analyses of DTIs were conducted, leading to the selection of 6 out of 380 DTIs identified by MDDeePred for further analyses. The physicochemical properties, lipophilicity, water solubility, drug-likeness and medicinal chemistry properties of the drug candidates and approved drugs for advanced stage HCC (lenvatinib, regorafenib, and sorafenib) were meticulously and curated. The majority of drug candidates fell within conventional ranges in terms of drug properties and demonstrated target docking abilities. Our findings revealed the binding efficiency of selected drug compounds to identified targets associated with

HCC. As a result, small molecules were identified that can be further evaluated experimentally as potential drug candidates in HCC. This study also highlights the importance of the MDeePred deep learning tool in *in silico* drug repurposing studies in cancer treatment.

Keywords: Drug candidate, drug repurposing, hepatocellular carcinoma, machine learning, MDeePred

Hepatoselüler karsinom (HCC), sınırlı tedavi seçenekleri nedeniyle yüksek mortalite oranına sahip, en sık görülen primer karaciğer kanseridir. Sistemik ilaç tedavileri hastanın hayatta kalma oranını artırır ve sıklıkla yaşam süresini birkaç ay uzatır. Yeni küçük moleküllü kemoterapötiklerin geliştirilmesi hem zaman alıcı hem de maliyetlidir. Bu nedenle ilacın yeniden kullanılması, bu ölümcül hastalık için yeni tedavi seçeneklerinin belirlenmesi ve uygulanmasında etkili bir strateji olarak kullanılıyor. Bu çalışmanın amacı, MDeePred makine öğrenme aracını kullanarak mevcut bileşiklerin yeniden kullanılması yoluyla HCC tedavisi için potansiyel ilaç adaylarını belirlemektir. Açık hedef platformu, UniProt, ChEMBL ve ExPasy veritabanları, MDeePred'in ilaç-hedef etkileşimlerini (DTI'ler) tahmin etmesi için bir veri kümesi oluşturmak üzere kullanıldı. DTI'ların zenginleştirme analizleri gerçekleştirildi ve MDeePred tarafından tanımlanan 380 DTI'dan 6'sının daha ileri analizler için seçilmesi sağlandı. İlaç adaylarının ve ileri evre HCC için onaylı ilaçların (lenvatinib, regorafenib ve sorafenib) fizikokimyasal özellikleri, lipofilikliği, suda çözünürlüğü, ilaca benzerliği ve tıbbi kimya özellikleri titizlikle belirlendi ve küratörlendi. İlaç adaylarının çoğunluğu, ilaç özellikleri açısından geleneksel aralıklara düştü ve hedef yerleştirme yetenekleri gösterdi. Bulgularımız, seçilen ilaç

bileşiklerinin HCC ile ilişkili belirlenen hedeflere bağlanma etkinliğini ortaya çıkardı. Sonuç olarak HCC'de potansiyel ilaç adayı olarak deneysel olarak daha fazla değerlendirilebilecek küçük moleküller belirlendi. Bu çalışma aynı zamanda kanser tedavisinde ilaç yeniden kullanım çalışmalarında MDeePred derin öğrenme aracının önemini de vurgulamaktadır.

Anahtar Sözcükler: İlaç aday molekülleri, ilaç yeniden konumlandırma, hepatoselüler karsinoma, makine öğrenimi, MDeePred

## ACKNOWLEDGMENTS

First of all, I would like to express my deepest gratitude to my advisors Asst. Prof. Dr. Burçak Otlu Sarıtař, Prof. Dr. Rengül Çetin-Atalay, and Prof. Dr. Mehmet Volkan Atalay, who supported and guided me throughout this thesis and made this study possible, for their patience and support.

I would like to express my special thanks to my understanding thesis committee members, Prof. Dr. Erden Banođlu ve Assistant Prof. Dr. Aybar Can Acar, who supported me throughout my thesis process.

I would like to thank to jury members of the examination committee, Assoc. Prof. Dr. Yeřim Aydın Son and Assoc. Prof. Dr. Özlen Konu Karakayalı, for their help.

I would like to thank Assist. Prof. Dr. Ahmet Süreyya Rifaiođlu for being with me with his patience, endless support, knowledge and experience.

I would like to thank Orçun Yılmaz and Batıhan Konuk for their help.

I would like to express my endless gratitude to Dr. Seda řirin for her endless love, support and help. At the same time, I would like to express my sincere gratitude for being more than just a friend to me, but for being like a sister to me and for her never-ending encouragement when I was feeling down. I could not have achieved this success without her tremendous support and friendship.

Throughout this journey, I would like to express my deepest gratitude to my beloved mother řenay Bařer and my beloved father Ufuk Bařer for their unconditional love, support and endless belief in me in my academic life and in all the decisions I have made throughout my life.

## CHAPTER 1

### INTRODUCTION

#### 1.1. Cancer

Cancer, the largest cause of mortality worldwide, is defined by uncontrolled cell proliferation and the tendency to spread to other parts of the body. It is caused by both hereditary factors and exogenous carcinogens, which might be physical, chemical, or biological (Emaduldeen et al., 2022). Worldwide, cancer incidence and mortality rates vary. Because of lifestyle and demographic factors, developed regions have high rates. For example, according to the most recent GLOBOCAN forecasts, there will be a high global cancer burden in 2020, with 19.3 million novel cases and 10.0 million deaths, with breast cancer emerging as the most common cancer worldwide in terms of diagnosis (Sung et al., 2021). Lung cancer was the primary cause of cancer death, accounting for around 1.8 million fatalities (18.7% of total), followed by colorectal cancer (9.3% of total), liver cancer (7.8% of total), female breast cancer (6.9% of total), and stomach cancer (6.8% of total) (Bray et al., 2024). One of the most significant factors in cancer prevention and early detection strategies are lifestyle factors, including factors such as smoking, obesity and alcohol intake (Jazieh et al., 2023). Considering factors such as cancer development, epidemiology and risk factors; since cancer has a complex structure, the importance and necessity of increasing special public health strategies and conducting continuous research to reduce the occurrence and impact of cancer all over the world are emphasized.

#### 1.2. Liver Cancer

Liver cancer, which originates in liver cells (Figure 1), is a serious global health issue due to its increasing prevalence and high mortality rates. Liver cancer is the eighth most common cancer type and ranks third in cancer deaths. Moreover, hepatocellular carcinoma (HCC) is the most common type of liver cancer (Chidambaranathan-Reghupaty et al., 2021; Wang et al., 2024a). Research indicates an increasing trend in the frequency of liver cancer in various regions, which can be related to several reasons such as the hepatitis B viruses and hepatitis C viruses and lifestyle-related risks including obesity and alcoholism (Huang et al., 2021). North Africa and East and Southeast Asia have the highest rates of liver cancer (Parra et al., 2023).

Figure 1: Location of the liver within the body

### 1.3. Hepatocellular Carcinoma (HCC)

HCC is the most prevalent form of primary liver cancer (accounting for 80–90% of cases) and is the most common cause of cancer-related deaths globally (Kim et al., 2024). In Western populations, recent studies have revealed a significant global variation in HCC incidence, because of primarily to varying risk factors such as aflatoxin exposure, alcohol consumption, chronic viral hepatitis (B and C), and the rising prevalence of non-alcoholic fatty liver disease (NAFLD) (Lampimukhi et al., 2023; Llovet et al., 2021a).

Due to the high frequency of hepatitis B and hepatitis C infections as well as dietary aflatoxins, the incidence of HCC is especially high in sub-Saharan Africa and East Asia. On the other hand, the number of cases in the US has been comparatively lower, despite the fact that it is rising as a result of increased rates of metabolic syndrome and obesity, both of which are major risk factors for HCC linked to NAFLD (Antwi et al., 2022; Kew, 2013; Michelotti et al., 2021).

In addition, it has been shown that there are gender variations in the prevalence of HCC, with males having higher rates than women. These differences may be caused by biological variables as well as differences in susceptibility to risk factors including tobacco and alcohol (Manieri et al., 2019; Zhang et al., 2021).

However, detecting HCC remains difficult since it has a complicated pathophysiology and a range of genetic, environmental, and viral causes (Parra et al., 2023).

## 1.4. Risk Factors

HCC is predominantly caused by a variety of well-defined risk factors. It has long been known that chronic viral infections, for example, hepatitis B (HBV) and hepatitis C (HCV), have a significant role in the development of HCC, especially in areas where these diseases are endemic (Yang et al., 2023).

Drinking alcohol is another important risk factor that can exacerbate the hepatocarcinogenic process, particularly when paired with viral hepatitis. Alcohol is a major factor in HCC risk because of its detrimental effects and interactions with other liver illnesses, such as hepatitis and aflatoxin exposure (Jacob et al., 2023).

Similarly, the risk of HCC is greatly increased by exposure to aflatoxins, strong liver carcinogens present in contaminated food sources, especially in developing nations (Dhandayuthapani et al., 2022).

NAFLD and more serious type of NAFLD, non-alcoholic steatohepatitis (NASH), have recently become an important risk factors for HCC, especially in Western nations where type 2 diabetes and obesity are common (Llovet et al., 2021a).

Genetic predispositions are also important in HCC susceptibility, with particular genetic mutations and family clustering identified as major risk factors. Advances in genetic and molecular profiling are helping to understand the complicated relationships between hereditary variables and environmental exposures in the formation of HCC (Yang et al., 2023).

In general, identifying the risk factors is critical for establishing focused prevention and treatment methods for HCC, with the goal of reducing the worldwide burden.

### 1.4.1. Chronic viral infections: Hepatitis B virus (HBV) infections

HBV is a severe worldwide health concern, characterized as a DNA virus that primarily targets liver cells (hepatocytes) and can cause chronic infection. Globally, it is forecasted that nearly 257 million individuals have HBV infection chronically. The life cycle of virus includes a unique replication process involving the transformation of its covalently closed circular DNA (cccDNA) from its relaxed circular DNA (rcDNA), which serves as a template for viral replication and protein production (Wei & Ploss, 2021). Surface antigens (S-HBsAg, M-HBsAg, and L-HBsAg), the small, medium, and large size surface antigens, are incorporated as transmembrane proteins in a lipid bilayer that forms the envelope of HBV. The envelope encases a nucleocapsid composed of 120 core proteins dimers (HBcAg), which contains the viral genome and polymerase (HBVPol). HBV is divided into 9 genotypes (A-I), one hypothetical genotype (J), and at least 35 subgroups (Campos-Valdez et al., 2021). HBV has the ability to interact with tumor suppression genes and oncogenes by integrating into host chromosomes. Consequently, severe fibrosis is not an essential requirement for HBV-induced HCC to arise (Kaur et al., 2022).

Hepatocellular carcinogenesis can be induced by HBV infection through indirect or direct mechanisms. In addition to this, through integration into host genes or inducing mutations, HBV can promote epigenetic remodeling of host DNA, which can lead to chromosomal remodeling and the aberrant expression of tumor suppressor and oncogene genes. It can also enhance the instability of the genome of the host cell (Li et al., 2021). Through the regulation of cell metabolism, activation of many cancer-related signaling pathways, and the regulation of other mechanisms, it can also lead to the malignant transformation of liver cells. On the other hand, HBV infection-induced chronic inflammation alters the liver microenvironment through interactions between the virus and innate immune cells and adaptive immune cells. These interactions help the virus evade immune surveillance and progress the disease from inflammation to tumor formation (Jiang et al., 2021).

The global incidence of HBV varies significantly, with high rates in parts of Asia and sub-Saharan Africa, where the virus is often transferred from mother to child during birth or in early childhood. In these areas, the incidence of chronic HBV infection can lead to a substantial burden of liver disease and cancer (Chuang et al., 2022).

#### *1.4.2. Chronic viral infections: Hepatitis C virus (HCV) infections*

HCV is surrounded by envelope, positive-sense, 9.6 kb single-stranded RNA virus with highly conserved 5' and 3' untranslated sequences. HCV mainly infects hepatocytes, as the expression of essential entry receptors and liver-specific cellular host factors (miRNA-122) required for viral replication occurs in hepatocytes (D'souza et al., 2020). HCV is a bloodborne disease that affects only the liver specifically. The majority of people infected with HCV are unable to remove the infection by itself, resulting in a lifelong chronic condition. Long-term liver inflammation caused by HCV leads to the development of advanced liver diseases such as cirrhosis, liver fibrosis, and HCC, resulting in death (Dash et al., 2020).

HCV proteins can directly activate mitogenic pathways, prevent cell death and increase ROS production. Furthermore, HCV initiates a persistent inflammatory process by causing the accumulation of lymphocytes in the liver and the production of various cytokines such as  $LT\alpha$  and  $LT\beta$ , which are closely associated with the development of HCC. Chronic inflammation increases ROS generation, which is thought to be a major cause of genetic alterations (Ivanov et al., 2017). ROS causes activation of the TGF- $\beta$  pathway, leading to activation of hepatic stellate cells and fibrogenesis. TGF- $\beta$ , together with TLR4, has a critical role in epithelial-mesenchymal transition. HCV disrupts host lipid metabolism, causing fat accumulation in the liver, and this condition is associated with HCC in many patients. Additionally, HCV can also trigger angiogenic and metastatic pathways. It has recently been determined that polymorphisms in the DEPDC5 and MICA genes increase the risk of developing HCC (Vescova et al., 2016).

The global incidence of HCV varies, with high prevalence rates in some areas of Eastern Europe, Sub-Saharan Africa and East Asia, primarily due to differences in

exposure to risk factors such as unsafe injection practices and blood transfusions. The burden of disease is further compounded by HCV's association with increased risks of development of liver cirrhosis and HCC, particularly in individuals with longstanding chronic infections (Roudot-Thoraval et al., 2021). Roughly, 71 million individuals have currently HCV infections. Only 20-30% of these people develop liver cirrhosis. In addition, 1-4% of patients with cirrhosis develop HCC each year (Dash et al., 2020).

#### *1.4.3. Aflatoxin B1*

Exposure to toxins such as aflatoxin, liver viral infections, and chronic hepatitis are linked to the progression of HCC. Aflatoxin, a metabolite of mold in the environment, has been found to be widespread in nature (Mungamuri et al., 2020). Its potential for causing harm is obvious. There are around 18 known aflatoxins, but those of particular concern are AFB 1, AFB 2, AFG 1, AFG 2, AFM 1, and AFM 2 (Awuchi et al., 2020).

Aflatoxin B1 (AFB1), produced primarily by *Aspergillus* species, is a potent carcinogen known to contaminate various food products, posing serious health risks, particularly liver cancer in humans and animals. AFB1 undergoes metabolic activation in the liver, where it is converted by cytochrome P450 enzymes into a reactive epoxide form that can form adducts with DNA, leading to mutations and the initiation of cancer (Min et al., 2021; Song et al., 2022). Researches show that AFB1 metabolites bind to DNA by alkylation of bases, leading to changes in the cell cycle and the tumor suppressor gene p53 mutation (Cai et al. 2020). The arginine to serine (G to T) mutation occurring at codon 249 of the p53 tumor suppressor gene (R249S; 249ser mutation) is specific to aflatoxin exposure and has been detected in 64% of HCC patients (Kew, 2023; Villar et al., 2012). AFB1 also induces oxidative stress and inflammatory responses, which further contribute to its toxicity and carcinogenicity. The generation of reactive oxygen species (ROS) and consequent oxidative damage are key mechanisms by which AFB1 exerts its harmful effects, leading to a cascade of cellular events that compromise cellular integrity and function (Ma et al., 2021).

The threat of AFB1 is globally recognized, with higher exposure rates in regions with hot and humid climates that promote fungal growth on crops like grains and nuts (Alameri et al., 2023). The incidence of AFB1-related health issues, such as HCC, is particularly high in parts of Africa and Asia due to dietary exposure to contaminated foodstuffs. Despite efforts to mitigate AFB1 contamination, it remains a significant challenge due to its stability and prevalence in staple foods (Hamid et al. 2013).

#### *1.4.4. Alcohol*

Alcohol is categorized by the International Agency for Research on Cancer as a category 1 carcinogen (Matsushita and Takaki, 2019). Alcohol consumption is a significant risk factor for HCC, the most frequent type of liver cancer. Chronic alcohol consumption leads to liver damage, including cirrhosis, fibrosis, acute/chronic hepatitis, and fatty liver, which are significant precursors to HCC. Alcohol metabolites, particularly acetaldehyde, are directly hepatotoxic and contribute to

oxidative stress and inflammation, which promote mutagenesis and tumor development in the liver (Jacob et al., 2023). It has been claimed that alcohol misuse raises the relative risk of HCC by three to ten fold (Matsushita and Takaki, 2019).

The mechanism by which alcohol exacerbates liver disease involves the induction of chronic inflammation, impairment of the liver's natural defenses, and the promotion of a fibrogenic response in hepatic cells (Subramaniyan et al., 2021; Yu et al., 2022). Alcohol activates various mechanisms that lead to hepatocyte proliferation and cancer formation. These mechanisms include ethanol metabolism pathways that include acetaldehyde production and CYP2E1 induction. Both promote the formation of ROS, lipid peroxidation, and DNA strand breaks. Additionally, alcohol causes DNA hypomethylation and damage to the retinoic acid pathway, promoting oncogene activation and inducing cancer formation (Sidharthan and Kottillil, 2014; Taniai, 2020). Various host factors, such as gene polymorphisms (C282Y heterozygosity and CYP2E1 c2), lead to increased carcinogenesis. Iron deposition and neovascularization are associated with both alcoholic liver disease and HCC. In the end, the immune system plays a critical role; TLR4/NANOG stimulates the growth of alcohol-induced HCC, whereas NK cells provide protection (Sidharthan and Kottillil, 2014). These effects are magnified by alcohol's interaction with other risk factors such as viral hepatitis, obesity, and smoking (Huang et al., 2023; Yu et al., 2022).

Globally, the incidence of alcohol-related HCC varies, with higher rates in regions where heavy drinking is more prevalent. For instance, in Eastern Europe and parts of Asia, where alcohol consumption is significant, there is a correspondingly high rate of HCC (Cho et al., 2023; Lampimukhi et al., 2023). Genetic factors also contribute to the susceptibility to alcohol-related liver disease, with variations in genes related to alcohol metabolism and liver function affecting the risk of developing HCC (Buch et al., 2022).

#### *1.4.5. Non-alcoholic fatty liver disease (NAFLD)*

NAFLD is a common disease defined by excessive accumulation of fat in the liver without significant alcohol consumption. Metabolic diseases such as central obesity, excess blood sugar, high blood pressure, dyslipidemia, and liver dysfunction lead to NAFLD (Pouwels et al., 2022). It affects approximately 25% of the global population and is a significant contributor to liver-related morbidity and mortality (Powell et al., 2021). In recent decades, NAFLD has become known as one of the most common chronic liver disorders globally (Pouwels et al., 2022). NAFLD has become one of the leading causes of liver transplants, greatly increasing the risk of liver cancer, heart disease, and death.

The pathophysiology of NAFLD involves multiple interrelated processes, including insulin resistance, oxidative stress, lipotoxicity, and chronic inflammation. These factors contribute to the progression of NAFLD to more severe liver damage (Juanola et al., 2021). Environmental factors, particularly diet and lifestyle, play very significant roles in the incidence and progression of the disease.

NAFLD is defined as accumulation of 5% or more triglycerides in liver tissue (i.e. steatosis) in the absence of extreme alcohol intake and other liver problems (for example, chronic viral hepatitis or steatogenic drug use). This disease, along with steatosis and liver inflammation, can progress to a more serious condition called NASH, with or without fibrosis (Chrysavgis et al., 2022). NASH is a more advanced stage of the disease and, over time, causes inflammation and scar tissue to form in the liver. This condition can eventually result in cirrhosis and hepatocellular carcinoma (Samy et al., 2024) (Figure 2).

Figure 2: Non-alcoholic fatty liver disease spectrum

NAFLD was linked to 19.2% of HCC cases among Medicare patients in the United States (32.07% in inpatients and 20.22% outpatients), but HCV infection was linked to just 9.75%. Compared to HBV-associated HCC patients, NAFLD-associated HCC patients had a higher mortality rate (odds ratio 1.87;  $p < 0.001$ ) (Younossi and Henry, 2021).

Globally, the incidence of NAFLD is increasing, paralleling the rise in type 2 diabetes and obesity. This trend is particularly pronounced in Western countries but is also a growing concern in developing regions where Western diets are becoming more common (Gangopadhyay et al., 2022; Goshnell et al., 2024). Despite its prevalence, NAFLD often remains undiagnosed until serious liver damage has occurred, underscoring the need for better diagnostic and therapeutic strategies.

### 1.5. Diagnosis

HCC screening is vital for early detection and improving treatment outcomes, particularly in high-risk populations such as those with HBV infection or chronic liver diseases. Standard screening protocols often include semi-annual ultrasound

examinations and the measurement of alpha-fetoprotein (AFP), although AFP's sensitivity and specificity can vary significantly (Debes et al., 2021). Ultrasound (US) technique, which uses US waves to reveal anomalies in the liver, is effective in detecting liver lesions that are suspected to be HCC. AFP, a glycoprotein generated by the liver and detectable in the blood, is considered a tumor marker as high levels can be related with HCC. These two tests (US and AFP) are performed alone or together to rule out the existence of HCC in person who are at high risk of developing HCC (URL<sub>1</sub>).

Recent advances have expanded screening tools to include dynamic contrast-enhanced imaging techniques such as computed tomography (CT) scans and magnetic resonance imaging (MRI), which can detect smaller and early-stage tumors more effectively compared to US alone. However, the accessibility and cost of these advanced imaging methods can limit their routine use in some settings (Giustini et al., 2023).

Contrast-enhanced US (CEUS) is another diagnostic modality that offers real-time imaging advantages, particularly in differentiating HCC from other hepatic lesions. It is effective in patients with atypical radiological features or those who cannot undergo CT/MRI due to contraindications (Kale, 2021).

Emerging biomarkers and liquid biopsy techniques are under investigation to improve the early detection of HCC. These include circulating tumor DNA and other molecular markers that could potentially supplement traditional imaging and biochemical tests, providing a more comprehensive and early diagnosis (Manea et al., 2023).

Despite advancements, significant challenges remain in the accurate early diagnosis of HCC due to the disease's complexity and the subtlety of early-stage manifestations. This necessitates ongoing research into more sensitive diagnostic tools and the refinement of existing modalities to improve the prognosis and management of HCC (Nadarević et al., 2021; Wang and Wei, 2020).

## **1.6. Staging**

HCC staging is critical for guiding treatment decisions and predicting prognosis (Torimura & Iwamoto, 2021). The Barcelona Clinic Liver Cancer (BCLC) system is used for clinical staging of liver cancer. It was first proposed by Llovet JM in 1999 and updated by the American Association for the Study of Liver Disease in 2005 (Figure 3 and Figure 4).

Figure 3: BCLC staging and classification

Figure 4: BCLC staging and classification

The implementation of this system will assist in assessing the patient's condition, providing accurate treatment alternatives, and predicting the patient's prognosis (Sun et al., 2024). The BCLC staging system is a system that classifies liver cancer patients and divides patients into five different stages: stage 0 (very early), stage A (early), stage B (intermediate), stage C (advanced), and stage D (terminal). This system also provides treatment recommendations. These recommendations are based on factors such as liver function, number of tumor, tumor size, vascular invasion, portal hypertension, extrahepatic metastasis, and physical condition (Sun et al., 2024; Wang et al., 2024).

The need for accurate staging is underscored by the heterogeneous nature of HCC, where patients with the same stage can have different outcomes based on sub-stage factors and response to treatment. This has led to continuous updates and refinements in staging systems to better match therapeutic options with patient-specific tumor characteristics and liver function status, aiming to optimize outcomes and enhance quality of life for patients with HCC (Golfieri et al., 2019).

## **1.7. Treatment**

Various surgical and non-surgical approaches are used in the treatment of HCC. Surgical approaches include liver resection and liver transplantation. Liver resection provides long-term survival for anatomically limited tumors and remains the standard first-line therapy, while transplantation is preferred, especially for patients with chronic liver disease (Glantzounis et al., 2021; O'Leary et al., 2020).

Non-surgical approaches for HCC treatment include transarterial chemoembolization (TACE), transarterial radiation (TARE), percutaneous local ablation, and microwave ablation (MWA). TACE is considered the standard treatment options for intermediate-stage HCC, providing localized chemotherapy to tumors (Kotsifa et al., 2022). TARE is used to deliver high-dose radiation to tumors and can achieve complete response in some patients (Taylor et al., 2019). Percutaneous local ablation methods, including MWA and radiofrequency ablation (RFA), are particularly used for early-stage tumors (Chevallier et al., 2023). Systemic therapy options, such as tyrosine kinase inhibitors (TKIs) and immunotherapies, are widely used, with drugs like lenvatinib and sorafenib being prominent in this category (Marquardt et al., 2019; Meng et al., 2020).

In conclusion, the treatment of HCC involves a variety of surgical and non-surgical methods selected based on the patient's overall condition, tumor stage, and liver function, with various combinations expanding the treatment options for patients (Kawano et al., 2022).

### *1.7.1. Surgical approaches*

Surgical approaches in the treatment of HCC primarily include resection and liver transplantation. Resection is the preferred method for patients with early-stage HCC

and well-preserved liver function. This approach is indicated for tumors confined to one lobe of the liver without vascular invasion, offering a potential cure for those without significant cirrhosis (Sugawara & Hibi, 2021) (Figure 5).

Figure 5: Types of hepatic resection

Liver transplantation, on the other hand, addresses both the tumor and the underlying liver disease, making it the optimal treatment for patients with decompensated cirrhosis or tumors meeting the Milan criteria (a solitary tumor  $\leq 5$  cm or up to three nodules each  $\leq 3$  cm). Transplantation not only removes the tumor but also eliminates cirrhosis, significantly improving long-term survival rates (Kow, 2019).

Recent advancements in surgical techniques and patient selection criteria have expanded the applicability of these surgical treatments, leading to improved outcomes. Laparoscopic liver resection has become increasingly popular due to its minimally invasive nature, which reduces blood loss and shortens hospital stays while providing similar long-term oncologic outcomes as open resection (Wilson & Geller, 2019). Despite the advances, the decision between resection and transplantation must consider tumor characteristics, liver function, and patient performance status to ensure the best possible outcomes (Makary et al., 2020).

In conclusion, surgical resection and liver transplantation are the cornerstone treatment options for HCC, with each approach tailored to the patient's specific clinical condition, offering the best chance for long-term survival (Kow, 2019; Lurje et al., 2019).

### *1.7.2. Non surgical approaches*

Non-surgical approaches in the treatment of HCC include various methods tailored to the patient's overall condition and the stage of the tumor. TACE is considered the standard treatment option for intermediate-stage HCC, providing localized chemotherapy to tumors by blocking their blood supply, thus directly destroying tumor cells and enhancing the effect of chemotherapy (Llovet et al., 2021b). TARE delivers high doses of radiation to the tumor and can achieve complete responses in some patients, making it an effective alternative for those who do not respond to TACE (O'Leary et al., 2020).

Percutaneous local ablation methods, especially effective for early-stage HCC, contain RFA and MWA. RFA is effective in treating HCCs up to 3 cm in size, providing results equivalent to surgical resection. For larger tumors, a combination of TACE and RFA is recommended (Chevallier et al., 2023). RFA destroys tumor cells by heating them, while MWA can eliminate larger tumors more quickly and, when used with RFA, provides a broader ablation area (Luerken et al., 2022). MWA destroys tumor cells using high-frequency microwaves and typically operates faster than RFA (Glassberg et al., 2019). Systemic therapy options play a crucial role in managing advanced HCC. TKIs and immunotherapies are prominent in this category. Drugs like lenvatinib and sorafenib slow the progression of HCC and extend patient survival by inhibiting tumor growth and spread (Chami et al., 2023).

In conclusion, non-surgical approaches in HCC treatment are selected based on the tumor stage and the patient's overall condition. Methods such as TACE, TARE, RFA, and MWA, used in various combinations, expand treatment options and improve patient outcomes. These approaches are tailored to individual patient needs, allowing for the determination of the most suitable treatment strategy (Chami et al., 2023; Chevallier et al., 2023; Llovet et al., 2021; Luerken et al., 2022; Xu et al., 2019;).

### *1.7.3. Disadvantages of current treatments*

The treatment of HCC has several surgical and non-surgical approaches, each with its own disadvantages. Surgical approaches like resection and liver transplantation are often limited by the patient's overall health and liver function. Resection is only suitable for a small proportion of patients with anatomically confined tumors and well-preserved liver function; however, it often results in high recurrence rates (Ince et al., 2019). Liver transplantation, while potentially curative, is hindered by the limited availability of donor organs and significant waiting times, which can lead to disease progression (Wege et al., 2019).

Non-surgical approaches also come with challenges. TACE is effective for intermediate-stage HCC but can cause significant side effects such as postembolization syndrome, which includes pain, fever, and nausea (Kotsifa et al., 2022). TARE can achieve high tumor control but poses risks such as radiation-induced liver disease (Andreana et al., 2012).

Percutaneous local ablation methods, like MWA and RFA, are effective for small tumors but are limited by the size and position of the tumors, often leading to incomplete ablation and tumor recurrence (Luerken et al., 2022). MWA, while faster than RFA, can cause complications such as bile duct injury and bleeding (Esmail et al., 2020).

Systemic therapy, including TKIs and immunotherapies, often has limited efficacy due to the underlying liver disease and can cause significant side effects such as hypertension, hand-foot syndrome, and immune-related adverse events (Ghavimi et al., 2020; Sadagopan et al., 2024).

In conclusion, while surgical and non-surgical treatments for HCC provide critical options, they each have limitations and potential adverse effects (D'Alessio & Fulgenzi, 2021).

### 1.8. Drug Discovery

Drug discovery is a complex, lengthy, and costly process that involves identifying, synthesizing, characterizing, and screening compounds for therapeutic efficacy. Typically, it takes about 10-15 years and costs between \$1 billion and \$2.6 billion to develop a new medicine, from the early discovery phase to regulatory approval and market entry (Annett, 2021; Rennane et al., 2021; Sun et al., 2022). The drug discovery process includes several stages: target identification, lead compound discovery, optimization, preclinical testing, and clinical trials (Figure 6) (Deore et al., 2019).

Figure 6. The drug discovery process (created in biorender.com)

Despite technological developments, such as high-throughput screening and artificial intelligence, which aim to reduce time and cost, drug discovery remains an expensive and time-consuming endeavor. The high failure rate of candidate compounds during clinical trials contributes significantly to the overall cost (Chan et al., 2019). One of the major disadvantages is that only a small fraction of discovered compounds eventually becomes a marketed drug (Figure 7), leading to substantial financial risk for pharmaceutical companies (Berdigaliyev & Aljofan, 2020; DiMasi et al., 2003).

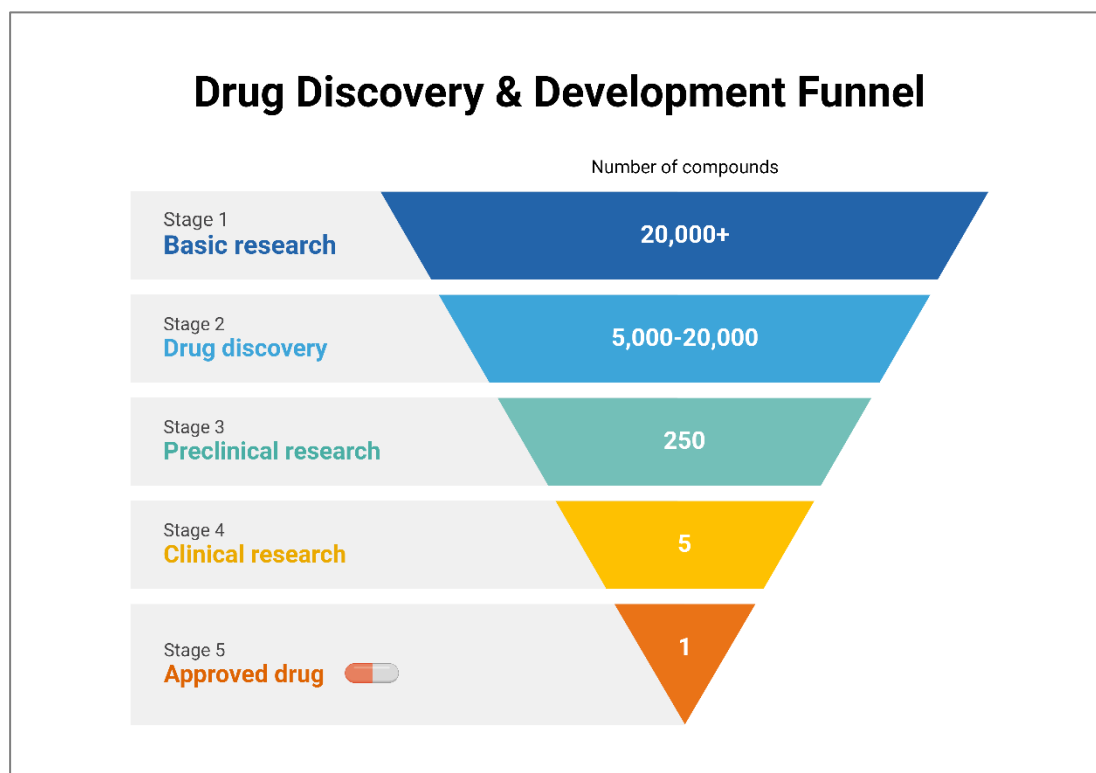

Figure 7. Drug discovery and development funnel (created in biorender.com)

Moreover, the increasing cost of research and development, along with regulatory requirements, further complicates the drug discovery process. Efforts to streamline and expedite this process include drug repurposing and the use of computational methods to predict therapeutic potential and side effects (Shaker et al., 2021; Vora et al., 2023). Despite these efforts, the inherent complexity and high attrition rate of drug development continue to pose significant challenges (Kumar et al., 2021; Waring et al., 2015).

In summary, drug discovery is a vital but challenging process with high costs, long timelines, and numerous obstacles, requiring innovative approaches to improve efficiency and success rates.

## **1.9. Drug Repurposing**

Drug repurposing is a strategy that seeks to find new therapeutic uses for existing, shelved, or clinically tested drugs, offering a promising alternative to traditional drug discovery methods. This approach is advantageous as it significantly reduces the time and cost involved in drug development since the pharmacokinetics, pharmacodynamics, and safety profiles of these drugs are already well-established, allowing pre-clinical studies to be bypassed (Babu, 2020). The process of drug repurposing involves systematic screenings, often supported by bioinformatics and computational technologies, to identify potential new indications for existing drugs (Tanoli, 2021a).

One of the primary benefits of drug repurposing is that it allows for quicker clinical deployment, reducing both developmental risk and the need for extensive early-phase clinical trials (Ng et al., 2021). This approach has proven particularly useful in response to urgent medical needs where existing drugs were rapidly evaluated for new applications (Bhagat & Butle, 2021; Low et al., 2020). The potential for significant cost savings and reduced development timelines makes drug repurposing an attractive strategy for both common and rare diseases (Verma et al., 2022).

## **1.10. Machine Learning (ML)**

ML has become a pivotal tool in drug repurposing, offering significant improvements in efficiency and accuracy. This approach leverages large datasets and advanced algorithms to identify novel therapeutic uses for existing drugs. The process involves systematic screenings supported by bioinformatics and computational technologies, such as deep learning, which help in predicting bioactivities and molecular properties with high accuracy (Ekins et al., 2019). ML methods can analyze gene expression profiles, chemical structures, and biological activities to uncover potential drug-disease associations, making the repurposing process more targeted and efficient (Figure 8) (Alharbi and Vakanski, 2023; Tanoli et al., 2021b; Walters and Vakanski, 2023; Wu and Wangi 2023).

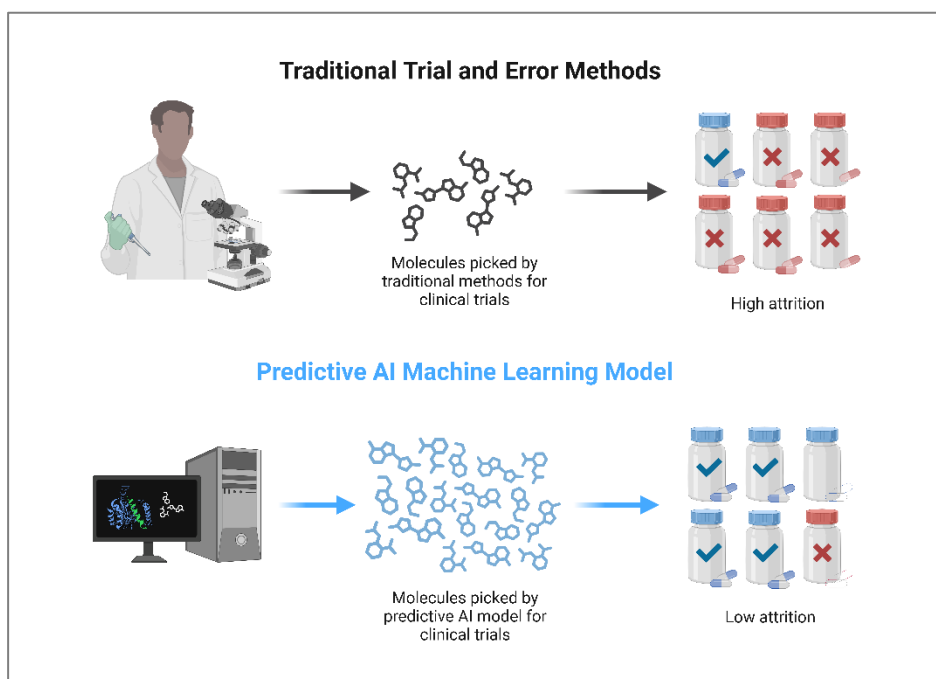

Figure 8. ML in drug discovery (created in biorender.com)

One of the primary advantages of using ML in drug repurposing is the reduction in time and cost associated with drug development. By utilizing existing safety and efficacy data, ML models can quickly identify promising candidates, thus accelerating the transition from discovery to clinical trials (Urbina et al., 2021). Moreover, ML approaches can handle vast amounts of heterogeneous data, integrating various types of biological, chemical, and clinical information to enhance prediction accuracy and uncover new therapeutic potentials (Issa et al., 2020). Ongoing advancements in ML techniques and the development of more sophisticated models continue to enhance the potential of drug repurposing, making it a vital strategy in modern drug discovery (Sherine Glory et al., 2022).

In summary, ML significantly enhances drug repurposing efforts by efficiently analyzing large datasets to identify new drug indications, thereby reducing development costs and timelines while overcoming traditional drug discovery challenges (Tanoli et al., 2021b).

### 1.11. MDeePred

MDeePred is an innovative deep learning-based approach for predicting binding affinity in drug discovery. This method leverages multi-channel protein featurization to identify interactions between bioactive small molecules and target proteins. MDeePred integrates various protein features, such as sequence, evolutionary,

structural, and physicochemical properties, into multiple 2D vectors, which are then fed into deep neural networks to predict compound-target protein interactions.

One of the primary advantages of MDDeePred is its ability to handle large datasets and integrate various biological, chemical, and clinical information to uncover new therapeutic potentials. This significantly reduces the time and cost associated with drug development, enabling faster clinical applications. The use of MDDeePred accelerates drug development processes and reduces costs due to its high prediction accuracy and extensive data integration capabilities.

In conclusion, MDDeePred is a powerful and innovative tool for drug discovery and repurposing, providing more accurate and effective predictions through deep learning and multi-channel protein featurization. This method plays a crucial role in modern pharmaceutical research, accelerating drug development processes and reducing costs (Rifaioğlu, 2020; Rifaioğlu et al., 2021).

### **1.12. *In Silico* Studies**

*In silico* studies aim to study biological processes using computer-aided simulations and modeling. These methods play an important role in the drug discovery process and save time and cost compared to traditional laboratory studies. Drug discovery is the process of finding and developing new therapeutic drugs and generally includes stages such as target identification, compound screening, optimization of candidate compounds, and preclinical and clinical testing. *In silico* approaches can be used at various stages of this process and are widely used in areas such as molecule screening, drug-target interaction prediction, and side effect analysis (Shaker et al., 2021).

Molecular screening and virtual screening methods help identify potential drug candidates by rapidly screening thousands of compounds in large databases. This process uses techniques such as molecular docking and molecular dynamics simulations to predict the potential of compounds to interact with biological targets. These methods accelerate the evaluation of potential candidates in the early stages of the drug discovery process and enable more targeted screening (Rognan, 2017).

Drug-target interactions are predicted through *in silico* modeling to evaluate critical parameters such as biological activity, binding affinity and specificity of candidate molecules. This evaluation increases the success rate of the drug discovery process and helps prevent possible failures in the preclinical stages (Terstappen & Reggiani, 2001).

In addition, *in silico* methods can reduce the risk of failure in clinical trials by predicting possible side effects and toxicity profiles. Pharmacokinetic and pharmacodynamic modeling allows the selection of safer and more effective compounds by simulating the absorption, distribution, metabolism, and excretion (ADME) processes of drug candidates (Butina et al., 2002).

As a result, *in silico* studies provide time and cost savings in the drug discovery process, allowing for rapid, efficient and targeted evaluation of potential drug candidates. These studies are used as a critical complementary tool alongside traditional methods, accelerating processes and increasing success rates.

#### *1.12.1. Enrichment analyses*

Enrichment analysis is an important statistical and bioinformatics method used to extract meaningful information from biological data. This analysis is used to determine whether certain categories are overrepresented in lists of biological entities such as gene sets, proteins, or metabolites. The main goal of enrichment analysis is to determine whether gene sets or biological pathways are overrepresented in a given condition over another, and this analysis is often used to discover disease-associated pathways, common gene interactions, or regulatory factors (Subramanian et al., 2005).

Gene set enrichment analysis (GSEA) is an important tool for interpreting gene expression data in terms of biological functions. GSEA allows genes to be grouped together by common biological functions, chromosomal locations, or regulatory mechanisms by considering gene sets. This method is very effective in revealing common biological pathways in various cancer-related data sets. For example, GSEA can reveal common biological pathways between independent studies in cases where single gene analyses show little similarity (Murohashi et al., 2010).

Because enrichment analysis often requires complex algorithms, it is common for these analyses to be performed using computer software. These software deliver results by running algorithms that are computationally demanding and often include statistical requirements such as multiple testing corrections (Tilford & Siemers, 2009). In addition, enrichment analyses used in the analysis of regulatory elements allow biological information to be extrapolated beyond gene sets and can also assess regulatory elements such as cytosine-phosphate-guanosine dinucleotide (CpG) sites, miRNAs, and transcription factors (García-Moreno et al., 2022).

In conclusion, enrichment analysis is a highly effective method for drawing meaningful conclusions from biological data. This analysis helps researchers better understand biological processes and develop hypotheses about diseases, treatment responses, or other biological conditions.

#### *1.12.2. SwissADME analysis*

SwissADME is a bioinformatics tool used in drug discovery and development processes, and plays an important role in evaluating the pharmacokinetic properties, drug-like properties and chemical suitability of drug candidates. This tool stands out as a critical tool in determining new therapeutic areas of existing drugs, especially in drug repurposing studies. SwissADME evaluates the bioavailability and efficacy of potential therapeutic molecules by predicting ADME properties from molecular structures (Daina et al., 2017).

One of the key features of SwissADME is the assessment of drug-like properties. SWISSADME evaluates whether a molecule is a drug candidate using drug-like rules such as “Lipinski’s Rule of Five”. This assessment plays a critical role in determining whether drugs are effective on biological targets (Azzam, 2023). In addition, SwissADME is an important tool for predicting pharmacokinetic properties. This tool predicts pharmacokinetic properties such as gastrointestinal absorption (GIA), blood brain barrier (BBB) permeability and P-gp substrate. Thus, it provides comprehensive information about the behavior of drugs in the human body (Daina et al., 2017). In addition, SwissADME also estimates the solubility and biological membrane permeability of molecules. These estimates are factors that directly affect the efficacy of drugs, and by estimating these parameters, SwissADME helps optimize bioavailability (Fan et al., 2022).

The role of SwissADME in drug repurposing involves the discovery of new uses for existing drugs for different diseases. In this process, the evaluation of ADME and drug-like properties provided by SwissADME provides a great advantage in identifying drugs that can be repurposed. Drug repurposing has the potential to provide therapeutic solutions with lower costs and shorter development times (Pushpakom et al., 2018). This tool allows drugs to be developed as more effective and safer therapeutic options.

### *1.12.3. Molecular docking*

Molecular docking is a computer-aided method based on three-dimensional structural analysis of interactions between small molecules (ligands) and large biomolecules (e.g. proteins). This method predicts how ligands bind to a given target molecule and determines the strength and nature of these interactions by calculating their binding energies. Molecular docking is often used in drug discovery and development and is an effective tool for modeling interactions between biological targets and potential drug candidates (Pinzi & Rastelli, 2019).

Molecular docking plays an important role in drug discovery processes. This method helps to understand the structural basis of drug interactions by predicting the binding affinity of a drug to its biological target. Docking is used for many purposes, such as determining structural activity relationships, measuring binding affinity, and predicting potential toxicity. At the same time, docking supports the design of new drug candidates by allowing the identification of molecules suitable for the active sites of target proteins (Agarwal & Mehrotra, 2016).

Molecular docking is also of great importance in drug repurposing. This method is used to evaluate the potential activities of existing drugs on different biological targets and thus helps to identify new therapeutic indications. Docking accelerates the process of discovering the reusability of drugs for various diseases and reduces development costs. This process contributes to the rapid development of new treatment options, especially for rare diseases and emergency situations (Shaikh et al., 2022).

Molecular docking also offers potential new uses by examining the effectiveness of existing chemotherapeutic drugs on new targets for various diseases, such as cancer. This method accelerates the clinical validation process by testing the effectiveness of clinically approved drugs against new biological targets (Kumar & Kumar, 2019).

### **1.13. The Aim of the Thesis**

This study aims to identify new candidate drug molecules for HCC therapeutics by repurposing compounds among existing compounds found in molecule databases. To achieve this goal, we used MDeePred, a recently developed deep learning-based method. Drug repurposing has the potential to rapidly expand available treatment options by shortening the development process and reducing costs. MDeePred shows promise in accelerating the drug discovery process using already-existing data and computational techniques. MDeePred's computational capabilities enable the identification of potential therapeutic targets and drug candidates with high accuracy rates. Our proposed approach holds promise in streamlining the drug discovery process by leveraging existing data and computational methods to identify potential therapeutic options not limited HCC but also for other cancers.

## CHAPTER 2

### MATERIALS & METHODS

This section consists of four parts in total. These are “collecting data from databases”, “preparation of data for MDeePred method and selection of the drug-target interactions”, “*in silico* validation of predicted small molecules targets hepatocellular carcinoma (HCC) transferase by SwissADME and molecular docking”, and “literature based validation of novel drug-target interaction predictions towards drug repurposing”. A schematic summary of the methods and techniques used in each part is provided in Figure 9.

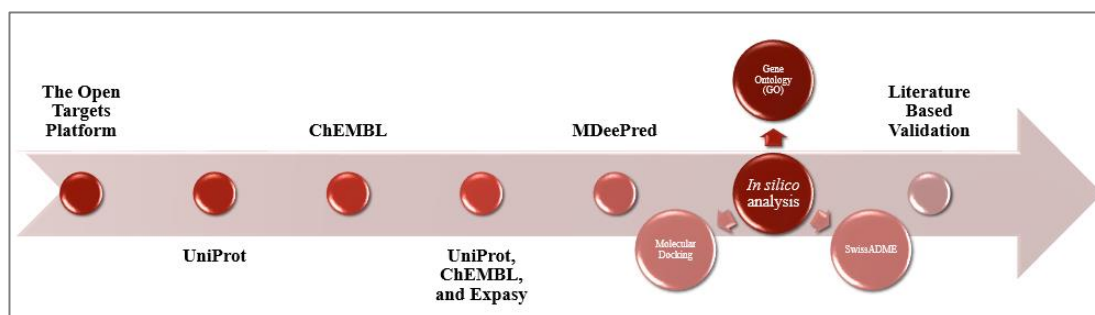

Figure 9. A schematic summary of the methods and techniques

#### 2.1. Collecting Data from Databases

In this study, HCC-related genes were systematically identified using the Open Targets Platform database, a comprehensive resource that integrates various types of evidence to establish the associations between genes and diseases (Koscielny et al., 2017). The Open Targets Platform is a great tool for identifying disease-associated genes. By combining genetic data, clinical results, and biological databases, it aids in the identification of putative genetic targets contributing to disease etiology (Ochoa et al., 2021). The focus was placed on genetic associations and somatic mutations as the primary data types to ensure the relevance and specificity of the identified genes to HCC. These data types were chosen because genetic associations provide insights into inherited predispositions to HCC, while somatic mutations highlight the acquired genetic alterations commonly observed in HCC tumors (Müller et al., 2020; Yang et al., 2023).

To refine the selection of HCC-related genes, we employed a quantitative approach. Specifically, we calculated the arithmetic mean of the relevance scores for genetic associations and somatic mutations. This method allowed us to integrate and balance the contributions of both inherited and somatic genetic factors, thus identifying the most pertinent genes involved in HCC pathogenesis. The genes with the highest combined scores were selected as the actual HCC-related genes for further analysis in this research (Ochoa et al., 2021).

The comprehensive list of these HCC-related genes, along with their respective relevance scores, is provided in Table S1.

The protein products of the selected HCC-related genes were validated using the UniProt database. UniProt is a comprehensive protein database that includes structural and functional information about proteins, providing detailed biological and biochemical functions (UniProt Consortium, 2019). In this study, UniProt was utilized to verify and characterize the proteins encoded by HCC-related genes.

To compile and validate the biochemical activity data of the proteins, referred to as targets in this thesis, encoded by each HCC-related gene, the ChEMBL database was employed. ChEMBL is a comprehensive chemical biology database that includes biological activities, particularly interactions with drugs. In other words, ChEMBL offers extensive details on small compounds with recognized biological activity and their potential for use in drug research. A manually curated compound-protein activity dataset was created using the ChEMBL database (Smirnov et al., 2018; Zdrzil et al., 2024). Several filters were applied to this dataset:

**Target Organism:** The dataset was filtered to include only data related to *Homo sapiens* (humans).

**Target Type:** Only data pertaining to single protein targets were selected.

**Assay Type:** The focus was on binding assays.

**Standard Unit:** Data were standardized to the molar (M) unit.

**Standard Type:** Half-maximal inhibitory concentration (IC<sub>50</sub>) measurements were used.

**Standard Relation:** Data were filtered based on standard relations such as = and < (Table 1).

Table 1: Filtration Criteria for Genes in ChEMBL Database

<b>Criteria</b>	<b>Filtration</b>
Target organism	<i>Homo sapiens</i>
Target type	Single protein
Assay type	Binding
Standard unit	Molar
Standard type	IC <sub>50</sub>
Standard relation	=, <
pChEMBL value	Exist

It was noted that the dataset contained repeated measurements from different experiments. To address this, the median bioactivity of each pair was calculated and used this as a single bioactivity measurement. Additionally, bioactivity measurements lacking the pChEMBL value, which represents the half-maximal response on a negative logarithmic scale, were excluded. A data point with a pChEMBL value shows that the record has been curated and is therefore considered reliable (Rifaioğlu et al., 2020).

After data filtering, the dataset was grouped using UniProt, ChEMBL, and ExPasy databases. The filtered gene set is provided in Table S3. This grouping facilitated a better understanding of the functional and biochemical properties of the HCC-related genes.

Finally, for the deep learning-based binding affinity prediction using the MDeePred tool, we selected the enzyme class of "HCC associated transferases" as our final dataset. This class served as an appropriate model to identify potential drug targets related to HCC.

This methodological approach allowed for accurate identification of the biochemical activities of HCC-related genes and the identification of potential therapeutic targets.

Transferases play crucial roles in modulating protein function and activity, processes that are indispensable in the context of carcinogenesis. These enzymes facilitate various post-translational modifications and are fundamental in regulating cellular pathways that drive cancer development and progression.

For instance, phosphate transferases regulate signal transduction pathways by phosphorylating proteins. This phosphorylation can activate or deactivate proteins, thereby controlling various cellular processes such as growth of cell, differentiation of cell, and apoptosis. Dysregulation of these pathways can lead to uncontrolled cell proliferation, a hallmark of cancer (Krause and Van Etten, 2005).

Similarly, methyl transferases and hydroxyl transferases play significant roles in epigenetic modifications and post-translational modifications of proteins. Methyl transferases are involved in the methylation of DNA and histones, which can alter the patterns of gene expression without altering the underlying DNA sequence. These epigenetic changes are crucial in cancer, where aberrant methylation patterns can cause the silence of tumor suppressor genes or the activation of oncogenes (Robertson, 2001). Hydroxyl transferases, on the other hand, contribute to the hydroxylation of proteins, influencing their stability, localization, and interaction with other cellular molecules. These modifications can have profound effects on cellular functions such as DNA repair, metabolism, and response to hypoxia, all of which are relevant to cancer biology (Ploumakis and Coleman, 2015).

By targeting transferases involved in these fundamental molecular mechanisms, we aim to gain insights into their potential as therapeutic targets and elucidate their roles in driving oncogenic processes.

## **2.2. Preparation of Data for MDeePred Method and Selection of the Drug-Target Interactions**

The MDeePred method was employed as a deep learning tool to identify the final drug candidates for HCC. According to Rifaioğlu et al. (2021), MDeePred utilizes bioactivity drug target data specifically focused on "transferases," a class of enzymes integral to various biochemical processes, including those related to cancer. This method involves training and testing datasets derived from the bioactivity profiles of these enzymes, which play crucial roles in the pathogenesis of HCC.

MDeePred leverages the Simplified Molecular Input Line Entry System (SMILES) to generate representations of chemical compounds. SMILES is a standardized notation that encodes a molecule's structure using short ASCII strings (Drefahl, 2011; Rifaioğlu et al., 2021). In MDeePred, each compound is depicted as a 200x200 pixel two-dimensional image derived from its SMILES representation. This transformation into 2D images allows the deep learning model to analyze the spatial and structural characteristics of the molecules more effectively.

The SMILES notation provides comprehensive information necessary for creating these 2D images, capturing the molecule's atomic connectivity and stereochemistry. This detailed representation ensures that the generated images accurately reflect the molecular structure, which is essential for the model to predict bioactivity with high accuracy (Moret et al., 2021; Quiros et al., 2018).

Open-access bioactivity databases supply the standardized SMILES data, which are crucial for constructing the training and testing datasets. These databases compile extensive bioactivity profiles for a wide range of compounds, allowing MDeePred to learn from a diverse set of molecular interactions. The training process involves exposing the deep learning model to a variety of bioactive compounds, enabling it to

discern patterns and relationships between molecular structures and their biological activities.

Through this sophisticated approach, MDDeePred can predict the bioactivity of new compounds, identifying potential drug candidates that may inhibit or modulate the activity of transferases involved in HCC. By converting chemical structures into image-based representations, MDDeePred harnesses the power of convolutional neural networks (CNNs) to process and analyze molecular features with high precision.

This innovative method provides a robust platform for drug discovery, facilitating the identification of effective therapeutic agents for HCC. By integrating advanced deep learning techniques with detailed molecular data, MDDeePred offers a powerful tool for accelerating the development of targeted cancer therapies.

Subsequently, to predict new drug-target interactions (DTI), we utilized the MDDeePred tool, which was specifically trained on the "HCC-related transferases" dataset, to screen over one million small molecule drug entries from the ChEMBL database (v24). ChEMBL is a comprehensive database providing biological activity data crucial for drug discovery and drug development processes (Gaulton et al., 2012).

MDDeePred employs deep learning algorithms to predict the potential effects of small molecule compounds on HCC-related transferases based on this dataset. During the screening process, each compound is transformed into a 200x200 pixel two-dimensional image derived from its SMILES notation, and these images are used as input for the deep learning model. This allows MDDeePred to analyze the structural characteristics of the compounds and make predictions about their bioactivity.

Following these comprehensive DTI predictions, a statistical measurement was conducted to determine the bioactivities of the small molecules on their target proteins. In this phase, each compound's potential interaction with the target proteins is evaluated based on specific biochemical and biophysical criteria. Statistical analyses are performed to enhance the accuracy of the model's predictions and minimize potential false positives.

To distinguish the common features of the target proteins and better understand their biological functions, an ontology-based enrichment analysis was performed. In this analysis, Gene Ontology (GO) terms were used to examine the molecular functions and biological processes of the proteins. Annotations that were overrepresented based on GO Molecular Function and Biological Process ontology terms were prioritized according to their statistical relevance to the target proteins (Jin et al., 2015).

Enrichment analysis is used to determine whether proteins involved in specific biological functions or processes are represented at a higher rate. This method helps identify critical biological pathways and functions in which HCC-related transferases play a role. These tests are essential for categorizing proteins into functional groups

and determining their involvement in specific biological processes (Zhang et al., 2017).

In conclusion, this methodology provides a significant step in identifying potential therapeutic targets for HCC and the small molecule drug candidates that can interact with them. The use of the MDDePred tool, integrating deep learning and bioinformatics methods, contributes to the development of new and effective strategies for HCC treatment.

### **2.3. *In Silico* Validation of Predicted Small Molecules Targets HCC Transferase by SwissADME and Molecular Docking**

Using the SwissADME online tool, we conducted a comprehensive analysis of small molecule drug candidate compounds targeting "HCC-related transferases." This analysis covered several critical aspects, including water solubility, physicochemical properties, lipophilicity, pharmacokinetics, drug-likeness, and medicinal chemistry friendliness. SwissADME provides a detailed assessment of these parameters, which are essential for understanding the potential efficacy and safety of the drug candidates.

The oral bioavailability and brain penetration potentials of the selected small molecules were evaluated using the oral bioavailability radar and the Brain Or Intestinal Estimated permeation method (BOILED Egg).

Oral bioavailability radar provides a visual representation of the drug-likeness of the molecules by plotting six key physicochemical properties: lipophilicity (LIPO), size (SIZE), polarity (POLAR), solubility (INSOLU), flexibility (FLEX), and saturation (INSATU). Each property is assessed to determine if the molecule falls within the optimal range for oral bioavailability. Compounds falling within the pink zone are considered to have favorable drug-likeness profiles, which indicate good oral bioavailability potential.

The BOILED Egg model was utilized to predict the passive GIA and brain penetration of the molecules. This model uses the lipophilicity (WLOGP) and the topological polar surface area (TPSA) of the compounds to classify them into three categories: high GIA, high brain penetration, or molecules that do not fall into either category. The resulting data is visualized on a 2D plot where molecules are placed within a 'yolk' (high probability of brain penetration) and/or 'white' (high probability of GIA) zone.

The physicochemical properties analyzed included molecular weight, hydrogen bond donors and acceptors, and TPSA. Lipophilicity was evaluated using multiple models such as XLogP3, WLogP, and MLogP, which predict the partition coefficient (log P) of compounds. Water solubility predictions were generated using the ESOL model, Ali model, and SILICOS-IT model, offering insights into the aqueous solubility of the compounds. These properties are crucial for predicting the absorption and distribution of the drug candidates in biological systems.

Pharmacokinetic properties were assessed to predict the behavior of the compounds in the body, including absorption, distribution, metabolism, excretion (ADME), and potential toxicity. Parameters such as blood-brain barrier permeability, GIA, and P-glycoprotein substrate status were considered. Additionally, the tool evaluated the potential for cytochrome P450 interactions, which are vital for understanding the metabolic stability and potential drug-drug interactions of the compounds.

Drug-likeness was evaluated using established rules such as Lipinski's Rule of Five, which considers factors like log P, molecular weight, hydrogen bond donors, and acceptors. Compounds were also assessed for compliance with other drug-likeness filters such as the Ghose filter, Veber rules, Egan rules, and Muegge rules. Medicinal chemistry friendliness was examined to identify potential structural alerts, pan-assay interference compounds (PAINS), and Brenk alerts, which can indicate undesirable chemical features that might interfere with biological assays (Daina et al., 2017).

Following the SwissADME analysis, molecular docking studies were performed using CB-Dock2, a web server that facilitates blind docking simulations. Blind docking was conducted by inputting the SDF file of each drug compound and the PDB files of five different target proteins into the server. CB-Dock2 identified potential binding sites on the target proteins and calculated the binding affinities of the drug candidates. In addition, molecular docking studies were performed for 6 small molecules and HCC drugs with kinase domain of all transferases.

The docking analysis focused on the docking poses with the highest Vina scores, indicating the strongest binding affinities. Vina scores provide an estimation of the binding free energy between the drug candidate and the target protein, with more negative scores indicating stronger predicted interactions. These docking poses were analyzed to identify the key interactions and binding conformations that could contribute to the efficacy of the drug candidates against HCC-related transferases.

This integrated approach, combining SwissADME and CB-Dock2, provided a thorough evaluation of the small molecule drug candidates, highlighting their potential as effective therapies for HCC by targeting specific transferases involved in the disease (Abhishek et al., 2023; Khachatryan et al., 2023).

In addition, we compared the values of our small compounds to lenvatinib, regorafenib, and sorafenib, which are presently used to treat advanced HCC.

#### **2.4. Literature Based Validation of Novel Drug-Target Interaction Predictions towards Drug Repurposing**

To support the DTI evidence presented in published scientific reports, we conducted a comprehensive literature review to validate the "HCC-related transferases" DTI pairs predicted by MDeePred. This step is crucial for corroborating the computational predictions with experimental data, ensuring the reliability and applicability of the

findings in a real-world context. The literature review focused on interactions between target proteins and drugs, gathering evidence that these interactions have been experimentally validated. We examined studies in the literature to collect empirical evidence supporting the drug-target interactions (DTIs) identified by MDeePred. By analyzing these studies, we aimed to confirm the predicted DTIs and enhance the confidence in our computational predictions.

## CHAPTER 3

### RESULTS

#### 3.1. Data Sets

Hepatocellular carcinoma (HCC) is one of the most common and fatal liver cancers worldwide, and genetic factors play a crucial role in the pathogenesis of the disease. In this context, a comprehensive analysis was performed using the Open Target Platform database to identify genes associated with HCC. The Open Target Platform is a powerful tool for identifying disease-gene associations by integrating various genetic and biomedical data sources. Using this platform to discover genes responsible for HCC is critical for better understanding the genetic basis of the illness and identifying particular genes and mutations that contribute to its progression. The Open Targets Platform allows for genetic associations, somatic mutations, biological pathways, and their linkages to diseases such as. This makes it easier to identify the genes that are directly responsible for the pathophysiology of HCC. As a result of this analysis, 7853 genes thought to be associated with HCC were identified. However, additional selection criteria were applied to more clearly understand the direct relationship of these genes with HCC and to reach more specific results by taking into account somatic mutations. As a result of this selective analysis, which took into account genetic relationships and somatic mutations, 673 genes were identified that were determined to be more strongly associated with HCC. These genes allow a better understanding of genetic factors that may potentially play a crucial role in HCC pathogenesis. Table S1 provides a detailed list of these 673 genes, providing more in-depth information on each gene's association with HCC. The selection of "genetic associations and somatic mutations" was critical in identifying genes directly related with HCC. Genetic associations indicate disease-linked variations and their possible involvement in the development of HCC, whereas somatic mutations indicate genetic alterations that occur inside cancer cells and directly contribute to tumor growth. Combining these two criteria makes the identification of HCC-associated genes more selective and therapeutically relevant. Thus, combining the two approaches not only reveals HCC-associated genes, but also improves our knowledge of their role in HCC. This stage is critical for identifying prospective biomarkers and therapeutic targets, which improves the accuracy and usefulness of the research.

Identification of these genes may make a significant contribution to the in-depth understanding of the molecular mechanisms of HCC. In particular, these genes may elucidate biological pathways and processes that play critical roles in the pathogenesis and progression of HCC.

Furthermore, identification of these genes allows the identification of potential therapeutic targets. The development of novel drugs that can be used in the treatment of HCC may be possible through the inhibition or modulation of these genes and their products. Further studies on these genes may offer new opportunities for early diagnosis of HCC and development of personalized treatment strategies.

Additionally, more comprehensive functional analyzes on these genes may contribute to a better understanding of the biological basis of HCC. This provides new information about the pathophysiology of the disease, allowing the development of innovative strategies for the prevention, early diagnosis and effective treatment of HCC.

In this study, genetic associations and somatic mutation scores were calculated by taking the arithmetic mean in order to more specifically determine the genes associated with HCC. Genetic association scores determine the associations of genes with HCC, while somatic mutation scores reflect the mutation frequencies of these genes observed in HCC patients. The arithmetic mean of both scores was used to more comprehensively evaluate the genes' associations with the disease.

Genes with arithmetic mean values of 0.25 and above were selected as genes with a significant relationship with HCC. The 0.25 cut-off value was used to filter genes highly related with HCC, ensuring that only the most important genes are picked while limiting false positives. This threshold balances the gene pool, preventing excessive noise but not rejecting viable candidates. By integrating genetic association and somatic mutation data, this cut-off improves research reliability and provides biologically meaningful results. As a result of this selection process, 106 genes with strong genetic and somatic associations with HCC were identified. These genes are critical to better understand the biological and molecular basis of HCC.

Table S2 details these 106 selected genes and their genetic associations and somatic mutation scores. In addition, Table 2 shows top 20 selected genes and their genetic associations and somatic mutation scores. This table presents each gene's association with HCC from both a genetic and somatic mutation perspective, providing researchers with more in-depth information about the pathogenesis of the disease.

Table 2: Top 20 Genes and Their Genetic Associations and Somatic Mutations Scores

Target gene	Target ID	Score.overall	Genetic association score	Somatic mutation score	Arithmetic mean
TP53	ENSG00000141510	1.0	1.0	1.0	1
CTNNB1	ENSG00000168036	1.0	1.0	1.0	1
TERT	ENSG00000164362	1.0	0.84	0.71	0.78
PIK3CA	ENSG00000121879	1.0	0.5	1.0	0.75

CDKN2A	ENSG00000147889	0.96	0.0	0.94	0.47
CREBBP	ENSG00000005339	0.94	0.0	0.93	0.46
NRAS	ENSG00000213281	0.93	0.0	0.92	0.46
IDH2	ENSG00000182054	0.93	0.0	0.91	0.46
ARID2	ENSG00000189079	0.90	0.0	0.87	0.43
GNAS	ENSG00000087460	0.86	0.0	0.86	0.43
KRAS	ENSG00000133703	0.83	0.0	0.82	0.41
FGFR1	ENSG00000077782	1.0	0.0	0.80	0.40
TSC2	ENSG00000103197	0.82	0.0	0.78	0.39
SF3B1	ENSG00000115524	0.79	0.0	0.76	0.38
APC	ENSG00000134982	0.86	0.0	0.75	0.37

Identification of these genes may help to better understand the molecular mechanisms of HCC and elucidate critical biological pathways associated with the disease. In

particular, it may be possible to utilize these genes as biomarkers for early HCC diagnosis and may also provide valuable information for monitoring disease progression and treatment response.

Additionally, further studies on these genes may contribute to the identification of new therapeutic targets. Inhibitors or modulators of these genes may allow the development of new strategies in the treatment of HCC. Therefore, detailed studies on the relationships of these genes with HCC may provide significant advances in the management of the disease.

In this research, the ChEMBL database was used to create a compound-protein activity array dataset for target proteins. The ChEMBL database is a comprehensive data source containing biological activities, pharmacological information and chemical structure information. Half-maximal inhibitory concentration ( $IC_{50}$ ) and pChEMBL values were taken into account in the selection of compounds for target proteins. While the  $IC_{50}$  value expresses the half-maximal inhibitory concentration of a compound, the pChEMBL value is the logarithmic form of this  $IC_{50}$  value and allows a more sensitive assessment of the compound's potency. In addition to these criteria, some filtering processes were applied and the details are reported in Table 1.

After the compound-protein activity array was generated, data were analyzed using ChEMBL, UniProt, and ExPasy databases. UniProt provides comprehensive information on protein sequences and functions, while the ExPasy database provides bioinformatics tools and resources. 46,400 data for 106 genes were grouped through these databases.

In the first stage of the analysis, it was checked whether the target proteins were enzymes or not. Then, the enzyme classes of the selected enzyme targets were determined. This step is critical to understanding the biological activities and roles of target proteins.

As a result, 22 target proteins (38,794 data in total) were identified as enzymes belonging to the transferase class. Transferases are enzymes that transfer functional groups from one molecule to another, and this class of enzymes may play a particularly important role in the biochemical pathways of HCC. Table 3 provides a detailed list of these targets identified as transferases and their associated data. Identification of these targets can make significant contributions to the identification of potential therapeutic targets in HCC treatment and new drug development processes.

Table 3: Identification of 22 Targets as Transferases

<b>Genes</b>	<b>ChEMBL ID</b>	<b>Genes Name</b>
TERT	CHEMBL2916	Telomerase reverse transcriptase
PIK3CA	CHEMBL4005	PI3-kinase p110-alpha subunit
MET	CHEMBL3717	Hepatocyte growth factor receptor
CREBBP	CHEMBL5747	CREB-binding protein
FGFR1	CHEMBL3650	Fibroblast growth factor receptor 1
ACVR2A	CHEMBL5616	Activin receptor type-2A
PRKACA	CHEMBL4101	cAMP-dependent protein kinase alpha-catalytic subunit
ATM	CHEMBL3797	Serine-protein kinase ATM
ROS1	CHEMBL5568	Proto-oncogene tyrosine-protein kinase ROS
AKT1	CHEMBL4282	Serine/threonine-protein kinase AKT
SETD2	CHEMBL3108647	Histone-lysine N-methyltransferase SETD2
FLT3	CHEMBL1974	Tyrosine-protein kinase receptor FLT3
KMT2A	CHEMBL1293299	Histone-lysine N-methyltransferase MLL
FLT4	CHEMBL1955	Vascular endothelial growth factor receptor 3
KIT	CHEMBL1936	Stem cell growth factor receptor
ERBB3	CHEMBL5838	Receptor tyrosine-protein kinase erbB-3
MAP3K1	CHEMBL3956	Mitogen-activated protein kinase kinase kinase 1
KDR	CHEMBL279	Vascular endothelial growth factor receptor 2
ALK	CHEMBL4247	ALK tyrosine kinase receptor
JAK3	CHEMBL2148	Tyrosine-protein kinase JAK3
RET	CHEMBL2041	Tyrosine-protein kinase receptor RET
NTRK1	CHEMBL2815	Nerve growth factor receptor Trk-A

The targets listed in Table 3 are essential to the pathophysiology of HCC because they influence the survival, proliferation, and metastasis of tumor cells. TERT and PIK3CA are associated with telomerase activity and the phosphatidylinositol 3-kinase (PI3K)/AKT signaling pathway, which promotes cell immortalization and survival. Tyrosine kinase receptors, such as MET, ALK, RET, and ROS1, promote HCC cell invasion and metastasis by controlling proliferation, migration, and differentiation. Epigenetic regulators such as CREBBP and SETD2 regulate gene expression via histone modifications, and their dysregulation leads to tumor growth. Signaling pathways including AKT1 and MAP3K1 affect cell survival and apoptosis. When they are active, they enhance tumor development. VEGF receptors (KDR, FLT4, FGFR1, and FLT3) and FGF receptors promote tumor angiogenesis by supplying vital nutrients for development. KIT and ERBB3 receptors control cellular development and differentiation, which promotes tumor proliferation. JAK3 and NTRK1 influence

signaling pathways and immunological responses, whereas ATM and KMT2A affect DNA repair and gene expression. Protein kinases like ACVR2A and PRKACA have roles in signaling pathways that control cell proliferation and differentiation, and their dysregulation contributes to tumor development. Given their critical roles in HCC, these genes are promising therapeutic targets, and inhibitors or modulators have the ability to stop or delay disease development (Cetin Atalay, 2015).

### **3.2. MDeePred Results**

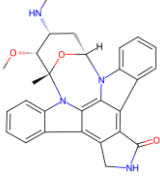

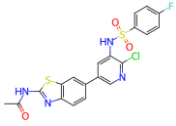

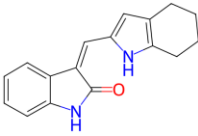

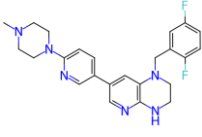

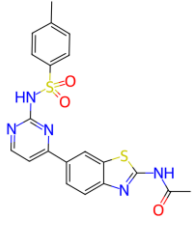

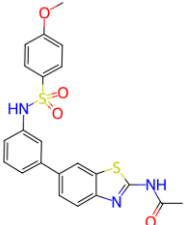

In this research, MDeePred technique was chosen to identify potential drug candidates for HCC. MDeePred is a method that predicts drug target interactions (DTI) using machine learning (ML) approaches. During the preparation of the datasets, data containing multiple data obtained from different experiments of the same gene for the same molecule were deduplicated. During the deduplication process, the median bioactivity value was used to handle duplicate data. This approach reduced noise in the data sets, resulting in more consistent and reliable results.

As a result of the deduplication process, the 38,794 data points initially available for 22 transferases were reduced to 30,821 data. This deduplicated data set was used in the training and testing stages of the model.

Following these preparations, the MDeePred process was carried out. MDeePred trained its model using the training dataset and then identified potential drug-target interactions by making predictions on the test dataset. This process resulted in 380 drug-target interactions (DTIs) associated with HCC (Table S3). These DTIs provide an important resource for identifying new drug candidates and target proteins that could potentially be used in the treatment of HCC.

Among 380 DTIs whose target-compound relationship has been studied in the literature, it was decided to select 6 DTIs to be used in further studies (Table 4). This selection was made considering that these DTIs have high potential in the treatment of HCC and are amenable to further experimental studies. These selected DTIs may contribute to the development of innovative therapeutic approaches in the treatment of HCC and allow significant advances in disease management.

Table 4: Selected Drug-Target Interactions List

Ligand (Drug/Compound)	Molecular Formula of Ligands	2D Structure of Ligands	Target Protein
CHEMBL388978 (Staurosporine)	C <sub>28</sub> H <sub>26</sub> N <sub>4</sub> O <sub>3</sub>		Tyrosine-protein kinase receptor FLT3 (FLT3)
CHEMBL1615189	C <sub>20</sub> H <sub>14</sub> ClFN <sub>4</sub> O <sub>3</sub> S <sub>2</sub>		PI3-kinase p110-alpha subunit (PIK3CA)
CHEMBL328029	C <sub>17</sub> H <sub>16</sub> N <sub>2</sub> O		Fibroblast growth factor receptor 1 (FGFR1)
CHEMBL1165499	C <sub>24</sub> H <sub>26</sub> F <sub>2</sub> N <sub>6</sub>		ALK tyrosine kinase receptor (ALK)
CHEMBL1773581	C <sub>20</sub> H <sub>17</sub> N <sub>5</sub> O <sub>3</sub> S <sub>2</sub>		Serine/threonine-protein kinase AKT (AKT1)
CHEMBL1773601	C <sub>22</sub> H <sub>19</sub> N <sub>3</sub> O <sub>4</sub> S <sub>2</sub>		Serine/threonine-protein kinase AKT (AKT1)

This study demonstrates that ML methods can be used effectively in identifying potential drug candidates for HCC and reveals that the MDeePred technique is a valuable tool in such research. Going forward, experimental studies on these DTIs may contribute to the development of new and effective therapeutic strategies in the treatment of HCC.

### **3.3. Enrichment Analyses of MDeePred Results**

Molecular function enrichment analysis for HCC (Hepatocellular carcinoma) is of great importance in understanding the molecular mechanisms of the disease, therapeutic targets, diagnosis and prognosis of the disease, and evaluating the response to treatment. These analyses serve as a critical tool in elucidating the biological basis of HCC and important pathways involved in the pathogenesis of the disease. Determining the molecular functions of HCC-associated genes and proteins is essential to identify potential therapeutic targets and develop innovative strategies in disease management.

In this study, enrichment analyses of the results obtained with the MDeePred technique were performed. Enrichment analyses enable assessing whether sets of genes and proteins are associated with specific biological functions or pathways. As a result of these analyses, HCC-associated molecular functions were grouped into two main categories: transmembrane receptor protein tyrosine kinase activity and adenosine triphosphate (ATP) binding.

Transmembrane receptor protein tyrosine kinase activity (Figure 10) refers to the activity of enzymes located on the cell surface that detect extracellular signals and initiate intracellular signal transduction pathways. These kinases play critical roles in many biological processes such as cell growth, differentiation, metabolism and apoptosis. In HCC, abnormalities in tyrosine kinase activity are important factors that promote the proliferation and metastasis of cancer cells. Therefore, tyrosine kinases attract attention as potential therapeutic molecules that can be targeted in the treatment of HCC.

Figure 10: Transmembrane receptor protein tyrosine kinase activity of protein set. (3): FGFR1, ALK and FLT3; (5): FGFR1, ALK, AKT1, FLT3 and PIK3CA

ATP binding (Figure 11) involves the binding of the ATP molecule to proteins and energy transfer processes. ATP is a central component of the cellular energy cycle and plays a vital role in regulating cellular activities and meeting energy needs. In HCC, disruption of ATP binding mechanisms can lead to significant changes in cell metabolism and energy balance. Therefore, proteins and pathways involved in ATP binding may be considered as potential targets in HCC treatment.

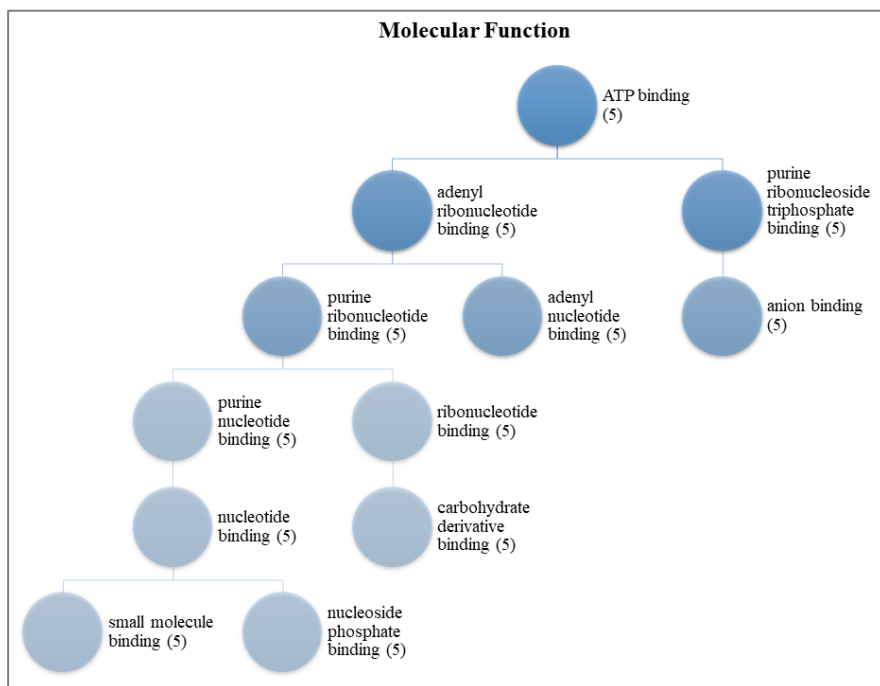

Figure 11: ATP binding of protein set. (5): FGFR1, ALK, AKT1, FLT3 and PIK3CA

Biological process analyzes have been used to understand the biological functions and pathways involved in HCC-related genes and proteins in a broader perspective. As a result of these analyses, 27 main biological process categories were identified (Figure 12). These categories cover a variety of biological processes such as cell cycle regulation, signal transduction, metabolic processes, cell death mechanisms, immune responses, and DNA repair. Understanding these processes provides in-depth insight into the pathogenesis and disease progression of HCC.

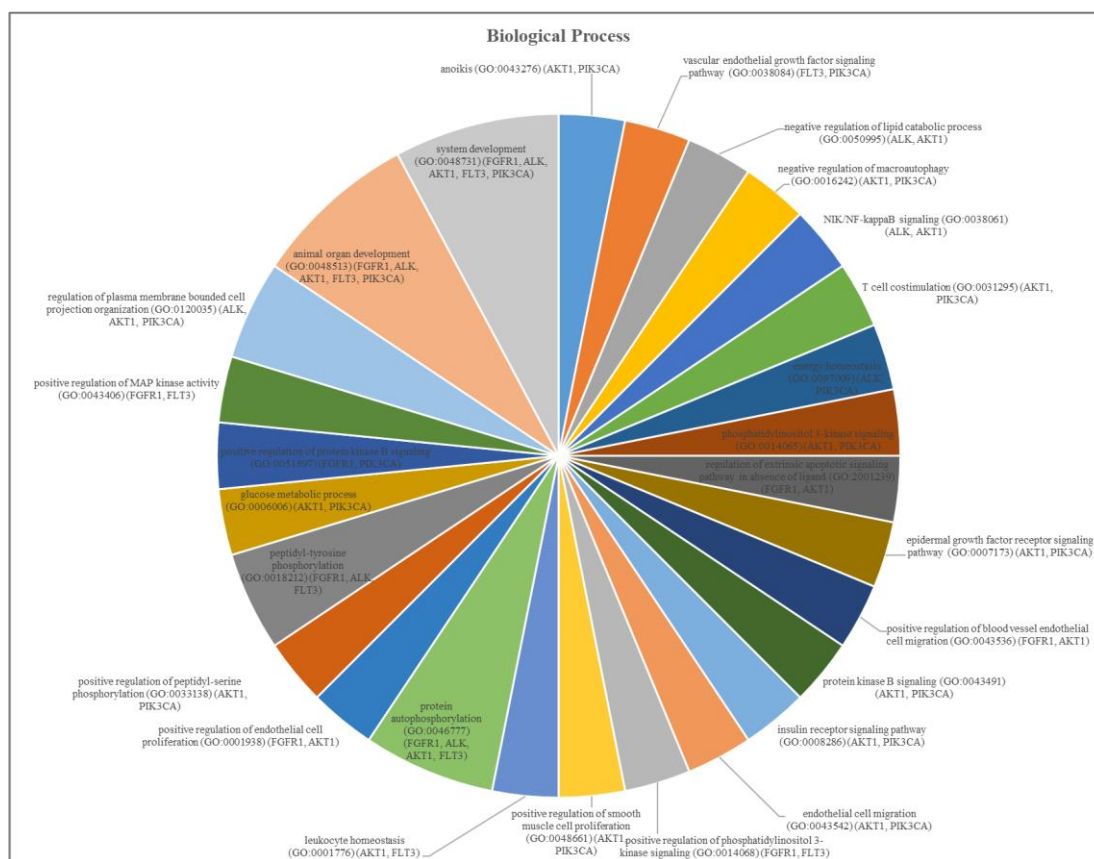

Figure 12: Biological process analyses of protein set

Molecular function enrichment analysis of HCC is a critical tool in understanding the biological basis and molecular mechanisms of this type of cancer. These analyzes allow the development of new approaches for early diagnosis of the disease, prognosis and evaluation of response to treatment. Consequently, molecular function enrichment analysis plays an important role in HCC research and treatment strategies.

### 3.4. SwissADME and Molecular Docking Results

SwissADME and molecular docking tools are critical in the process of evaluating, optimizing and selecting potential drug candidates for HCC treatment. These tools can contribute to the development of more effective and safer treatments by accelerating the drug development process. SwissADME provides important information in the drug design process by evaluating the pharmacokinetic and pharmacodynamic properties of drug candidates. Molecular docking simulates the interactions of drug candidates with target proteins and predicts the strength and specificity of these interactions.

The schematic diagram of oral bioavailability is a visual tool used to quickly evaluate the pharmacokinetic properties of a drug candidate. This diagram analyzes properties of potential drug candidates such as lipophilicity, size, polarity, insolubility, insaturation, and flexibility. These parameters affect the absorption in the gastrointestinal tract, passage into the systemic circulation and bioavailability of the drug candidate. Oral bioavailability predictions are particularly important in drug design and development because these properties can directly affect the effectiveness and safety of the drug. A schematic diagram showing the oral bioavailability of drug candidate compounds, lenvatinib, regorafenib, and sorafenib is presented in Figure 13.

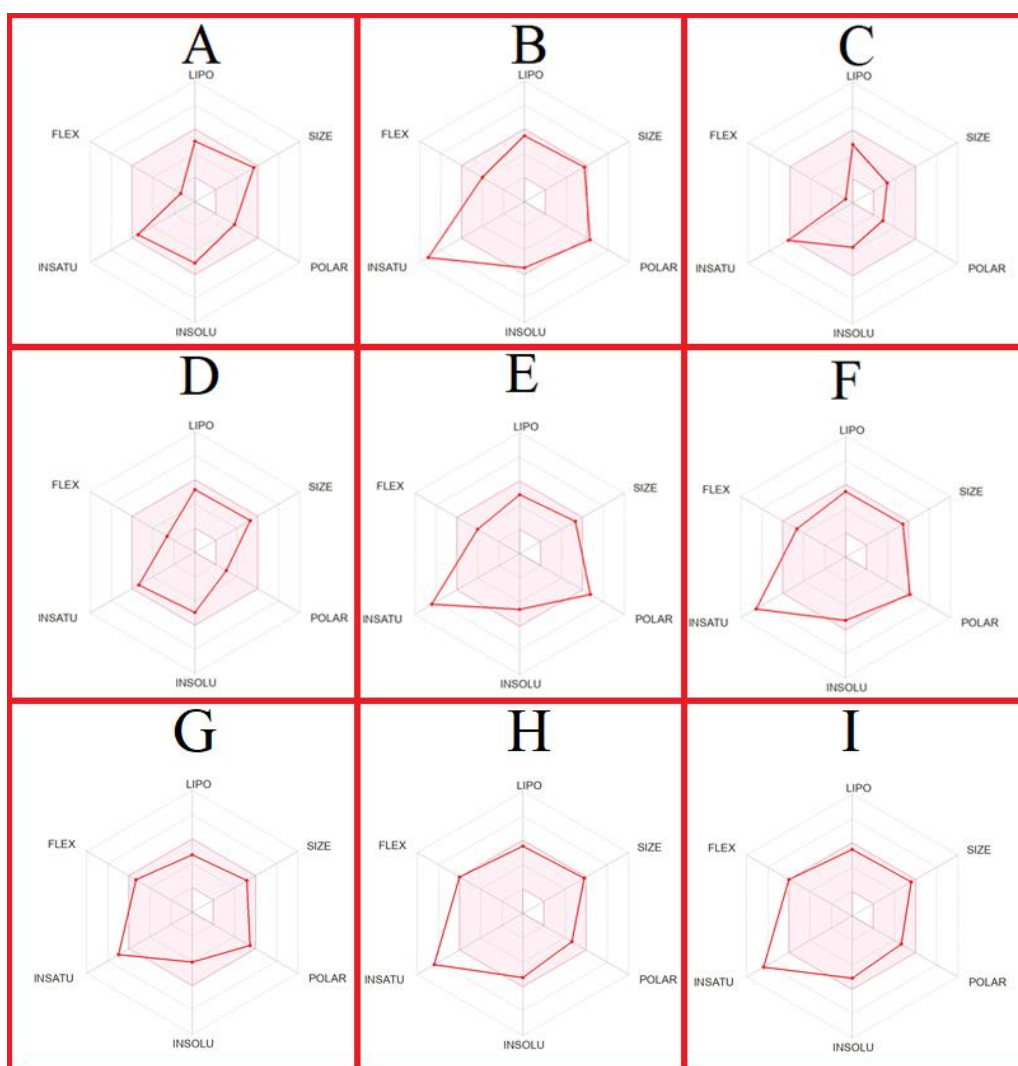

Figure 13: Schematic diagram of oral bioavailability of the drug candidate compounds and drugs. (A) CHEMBL388978. (B) CHEMBL1615189. (C) CHEMBL328029. (D) CHEMBL1165499. (E) CHEMBL1773581. (F) CHEMBL1773601 (G) Lenvatinib. (H) Regorafenib. (I) Sorafenib.

The BOILED Egg diagram is a graphical tool used to estimate the overall absorption, distribution, metabolism, and excretion (ADME) properties of a molecule. This diagram visually represents the gastrointestinal absorption (GIA) ability and likelihood of crossing the BBB of potential drug candidates. The BOILED Egg diagram is an important guide when evaluating the GIA and access to the central nervous system (CNS) of drug molecules. The BOILED Egg diagram of drug candidate compounds and approved HCC drugs is shown in Figure 14.

Figure 14: BOILED Egg diagram of the drug candidate compounds and drugs. (1) CHEMBL388978. (2) CHEMBL1615189. (3) CHEMBL328029. (4) CHEMBL1165499. (5) CHEMBL1773581. (6) CHEMBL1773601 (7) Lenvatinib. (8) Regorafenib. (9) Sorafenib.

Predictive findings regarding the physicochemical properties, lipophilicity, water solubility, drug-likeness and medicinal chemistry of drug candidate compounds and lenvatinib, regorafenib, and sorafenib are presented in detail in Table 5-9. These tables comprehensively evaluate the molecular properties of drug candidates and predict their potential therapeutic effects using this information.

Physicochemical properties: Includes properties such as molecular weight, polar surface area, hydrophobic and hydrophilic balance of molecules. These properties affect the drug's ability to cross cell membranes and reach the target (Table 5).

**Lipophilicity:** The degree of lipophilicity of molecules indicates their affinity for hydrophobic environments. High lipophilicity makes it easier to cross cell membranes, whereas excessive lipophilicity may increase the risk of toxicity (Table 6).

**Water Solubility:** The solubility of molecules in water is a critical factor in terms of bioavailability and distribution in the body. Low solubility may limit the absorption and effectiveness of the drug (Table 7).

**Drug Similarity:** The drug similarity of molecules is evaluated based on certain criteria such as Lipinski's Rules. These rules are used to predict the oral bioavailability and pharmacological activity of molecules (Table 8).

**Medicinal Chemistry:** The chemical structure and functional groups of molecules determine their potential biological activity and therapeutic effects (Table 9).

These analyzes are part of a comprehensive evaluation to identify the most appropriate drug candidates for the treatment of HCC. This process enables important steps towards drug development and contributes to finding safer and more effective treatments for patients.

Additionally, molecular docking analyzes were applied to 6 drug-target interactions, containing 5 different protein targets and 6 drug candidates, selected after MDDePred analysis and classification. In addition, molecular docking analyzes were applied to lenvatinib, regorafenib, and sorafenib. Molecular docking analyzes are used to predict how drug candidates dock at the binding sites of target proteins and the strength of these interactions. These analyzes examine the interaction of drug candidates with target proteins at the molecular level, providing a better understanding of their potential therapeutic effects.

Table 5: Physicochemical Properties of the Drug Candidate Compounds and Drugs

Drug candidate compounds and drugs*	CHEMBL388978	CHEMBL1615189	CHEMBL328029	CHEMBL1165499	CHEMBL1773581	CHEMBL1773601	Lenvatinib	Regorafenib	Sorafenib

Figure 15 shows the optimal positions of drug candidates for human HCC in docking into the binding sites of their target proteins. This visual details how each drug candidate interacts with the target protein and the key contact points in the binding site. Molecular docking analyzes produce a detailed profile of drug-target interactions by determining the binding energies of drug molecules (vina score), binding cavity volume ( $\text{\AA}^3$ ) and contact residues located in binding sites.

Figure 15: The best poses in the molecular docking of DTIs and drugs. (A) FGFR1 and CHEMBL328029. (B) ALK and CHEMBL1165499. (C) AKT1 and CHEMBL1773601. (D) AKT1 and CHEMBL1773581. (E) FLT3 and CHEMBL388978. (F) PIK3CA and CHEMBL1615189. (G) FGRF1 and levatinib. (H) PIK3CA and regorafenib. (I) PIK3CA and sorafenib.

Blue dotted lines for hydrogen bonds, yellow for electrostatic interactions, and grey for hydrophobic interactions, allows to observe how our drug compounds interact with target proteins.

In Table 10 and Table S4, the results of molecular docking analyzes of drug candidates and lenvatinib, regorafenib, and sorafenib are summarized. This table includes important parameters such as vina scores, binding cavity volume ( $\text{\AA}^3$ ) and contacting amino acid residues (Table S4) obtained for each drug candidate. The vina score indicates the binding affinity of the drug molecule with the target protein, with lower scores indicating stronger binding. Cavity volume ( $\text{\AA}^3$ ) refers to the physical size of the binding site, and these values are used to evaluate how well the drug molecule fits into the binding site. Contact residues indicate through which amino acid residues the drug molecule interacts with the target protein.

As a result of these molecular docking analyses, enzymes belonging to the transferase class of 6 DTI were identified as target proteins. These transferases are enzymes that play a critical role in the biochemical pathways of HCC, and drug candidates that interact with these enzymes can be evaluated as potential therapeutic agents. Table 10 presents details of these drug-target interactions, providing important information about the efficacy and safety of each drug candidate.

Table 10: Molecular Docking Results of Small Molecules-Transferases and Drugs-Transferases

Ligand (Drug/Compound)	Target Protein	Vina Score	Cavity Volume (Å <sup>3</sup> )
CHEMBL328029	FGFR1	-8.7	543

Sorafenib	FLT3	-10.3	832
Sorafenib	PIK3CA	-10.3	2313

In addition, in this study, molecular docking was performed to determine the binding affinities of six small molecules, identified as potential drug candidates for HCC, to the kinase domains of the targets of six DTIs. For three drug molecules (lenvatinib, regorafenib and sorafenib) currently used in the treatment of advanced HCC, binding

affinities to the kinase domains of the targets were also determined via molecular docking (Table 11 and Table S5).

Table 11: Molecular Docking Results of Small Molecules/Drugs-Kinase Domains of Transferases

<b>Ligand (Drug/compound)</b>	<b>Target Protein</b>	<b>Vina score</b>	<b>Cavity volume (Å<sup>3</sup>)</b>
CHEMBL328029	FGFR1	-10.5	1933

CHEMBL388978	FLT3	-9.2	805
Lenvatinib	FLT3	-8.3	2684
Regorafenib	FLT3	-10.0	2684
Sorafenib	FLT3	-9.8	805
CHEMBL1615189	PIK3CA	-9.5	3260
Lenvatinib	PIK3CA	-8.7	3260
Regorafenib	PIK3CA	-9.6	3260
Sorafenib	PIK3CA	-9.8	1188

Beyond the six DTIs, the binding affinities of the six small molecules, identified as potential drug candidates for HCC, were also determined for the kinase domains of all the targeted proteins within the scope of this study using molecular docking (Table S5).

The results of this study represent an important step towards identifying and optimizing new drug candidates that can be used in the treatment of HCC. Molecular docking analyzes can play a critical role in the drug development process, contributing to the development of more effective and safe treatments. Going forward, experimental studies on these results may enable the development of innovative therapeutic strategies in the treatment of HCC.

### 3.5. Literature Based Validation of Novel Drug-Target Interaction Predictions towards Drug Repurposing

A literature review of 380 DTIs found publications supporting the target-compound relationship of only 6 DTIs. These literature-supported interactions provide important information to evaluate the use of potential drug candidates in the treatment of HCC. Table 12 lists these literature-supported DTI estimates along with their references. This table contains literature validation of each interaction and IC<sub>50</sub> values obtained from the ChEMBL database.

Table 12: Literature Verified Selected DTI Prediction of MDeePred

Ligand (Drug/Compound)	Target Protein	Experimental Bioactivity IC <sub>50</sub> (nM)	Reference
CHEMBL328029	Fibroblast growth factor receptor 1 (FGFR1)	10500	Tinivella et al. (2022)
CHEMBL1165499	ALK tyrosine kinase receptor (ALK)	33	Das et al., (2021)
CHEMBL1773601	Serine/threonine-protein kinase AKT (AKT1)	1160	Jovanović et al. (2018)
CHEMBL1773581	Serine/threonine-protein kinase AKT (AKT1)	1260	Jovanović et al. (2018)
CHEMBL388978 (Staurosporine)	Tyrosine-protein kinase receptor FLT3 (FLT3)	1	Janssen et al. (2018)
CHEMBL1615189	PI3-kinase p110-alpha subunit (PIK3CA)	6.3	Jovanović et al. (2018)

IC<sub>50</sub> values indicate the concentration at which a compound inhibits the activity of a particular biological target by 50%. These values play a critical role in evaluating the effectiveness of a drug candidate. Lower IC<sub>50</sub> values indicate that the compound has a higher inhibitory potency on the target and therefore may be a more effective drug candidate.

Detailed examination of these 6 DTIs supported in the literature constitutes an important step to identify potential drug candidates that can be used in the treatment of HCC. Confirmation of these interactions would enable these drugs to be evaluated prospectively in clinical studies and experimental studies. Additionally, analysis of IC<sub>50</sub> values helps determine optimal dosages of these compounds and conduct toxicity assessments.

This research plays an important role in the process of identifying and optimizing potential drug candidates for the treatment of HCC. Identification of DTIs supported by the literature allows for a more comprehensive examination of the efficacy and safety profiles of these compounds. This contributes to the development of innovative and effective therapeutic strategies in the treatment of HCC.

## CHAPTER 4

### DISCUSSION

Hepatocellular carcinoma (HCC) is a prevalent malignant tumor in the digestive system. It holds the fifth position in terms of incidence and third in terms of fatality rate among global malignant tumors, posing a significant risk to health and survival. Liver cancer often develops unnoticed, and the majority of cases are identified at an intermediate or advanced stage, leading to a grim outlook (Tian et al., 2023). HCC is unquestionably a resistant kind of cancer, making therapy more difficult. Although systemic drug therapy has improved survival rates in HCC patients, the progress in treatment outcomes remains gradual and insufficient, particularly when compared to other cancers (Attia et al., 2020). Additionally, the process of developing new drugs is both a lengthy and expensive process. As stated by the Eastern Research Group (ERG), it typically takes 10-15 years, and the average success rate for the development of a new molecular entity is a mere 2.01% (Pan et al., 2022).

Drug repurposing, also known as “new uses for old drugs”, involves finding new applications for approved or experimental drugs that are not within the range of the original medical indication. The key benefit of this method is that the pharmacokinetic, pharmacodynamic, and toxicity profiles of the drugs have already been determined in the initial preclinical and phase I studies. As a result, these drugs can quickly advance to phase II and phase III clinical trials, significantly reducing the associated development costs (Zhang et al., 2020).

The goal of this thesis is to identify possible therapeutic compounds for HCC by repurposing current medication molecules using a machine learning (ML) approach named MDeePred. MDeePred is able to identify potential drug candidates for the targets, we conducted a drug-target interactions (DTIs) study on genes that responsible for HCC. We obtained 380 DTIs using the MDeePred method (Table S3). As a result of the literature review for 380 DTIs, 6 DTIs were selected further studies (Table 4). There are 5 different transferases related to HCC within 6 DTIs as mentioned below. These transferases are FGFR1, ALK, AKT1, FLT3, and PIK3CA. All of these transferases have important roles in a variety metabolic processes and any defect in them is effective in the formation and progression of HCC.

FGFR1 belongs to the type 4 receptor tyrosine kinase family (FGFR1–4), which binds to fibroblast growth factors (FGFs) (Krook et al., 2021). The interaction between the ligand and the FGF receptor is vital in governing various developmental processes during embryonic growth and is crucial for tissue repair and upholding tissue balance

in adults. When FGFs bind to any of these receptors, it triggers signal transduction through the induction of receptor dimerization, leading to subsequent downstream signaling events (Schultheis et al., 2014). Overexpression of FGFR1 has been found to have important roles in the HCC (Zhao et al., 2021).

Anaplastic lymphoma kinase (ALK) is a significant molecular target in the receptor tyrosine kinase family, holding vast relevance in drug discovery, particularly for cancer treatments. ALK is a member of the insulin receptor superfamily and has an important role in multiple malignancies, HCC being one of them. Research has indicated ALK's role in advancing cancer and metastasis, highlighting its importance as a top target for new anticancer drug development (Gowhari Shabgah et al., 2021; Jia et al., 2014).

AKT1, one of the well-preserved subtypes of protein kinase B (AKT), is a crucial component of the phosphatidylinositol 3-kinase (PI3K)-Akt signaling cascade. PI3K/Akt/mammalian target of the rapamycin (mTOR) signaling pathway promotes cell growth, invasion, angiogenesis, and prevents cell apoptosis in various cancers (Guo et al., 2019). Its malfunction is central to the emergence of a wide range of human cancers (Revathidevi and Munirajan, 2019). Initial research identified mutations and imbalances in the expression of the PI3K/Akt/mTOR signaling pathway in HCC (Sun et al., 2021). Loss of phosphatase and tensin homolog (PTEN) tumoursuppressor protein leads to hyperactivity in the PI3K/Akt pathway, which promotes cell survival and resistance to treatments in several malignancies, including liver cancer (Durmaz et al., 2016; Aydin et al., 2016).

FLT3 is a receptor tyrosine kinase expressed by immature hematopoietic cells. It is crucial for stem cell development and immune system functioning. Its ligand, produced by marrow stromal and other cells, collaborates with various growth factors to boost the growth of stem cells, dendritic cells, progenitor cells, and natural killer cells (Gilliland and Griffin, 2002). Given the decrease in tumor formation capacity in HCC cells after inhibiting FLT3 activity, it presents as a promising therapeutic target for HCC treatment (Aydin et al., 2016).

Receptor tyrosine kinase dependent PI3K are a family of lipid kinases. They are classified into three classes (Class I-A&B, II, and III) according to their substrate specificities and structural characteristics. In mammals, class I PI3Ks split further into subclasses IA and IB, differentiated by their regulatory methods. Class IA PI3Ks combine a p110 catalytic subunit with a p85 regulatory one. Three closely related class IA catalytic isoforms are encoded by the PIK3CA, PIK3CB, and PIK3CD genes: p110a, p110b, and p110d, as outlined by Verret et al. (2019). These PI3Ks are fundamental to starting the Akt/mTOR signaling pathway, governing crucial cellular functions and activities, such as cell growth, survival, movement, and metabolism. Therefore, PIK3CA is linked to the progression of various cancers, including HCC, positioning it as a potential therapeutic target (Rascio et al., 2021; Vique-Sanchez et al., 2022).

To conclude that since the aforementioned transferases (FGFR1, ALK, AKT1, FLT3 and PIK3CA) have an important role in the formation of HCC, it is important to find drug molecules that affect these transferases in the treatment of HCC.

Following the enrichment analyses, molecular functions were classified into two main categories: transmembrane receptor protein tyrosine kinase activity (Figure 10) and ATP binding (Figure 11). Meanwhile, analyses of biological processes were categorized into 27 primary groups (Figure 12). To conclude that, all transferases have kinase activity and ATP binding activity. As the 5 transferases of which we have explained above, kinases take part in important metabolic mechanisms in the cell, so any deterioration in their function causes HCC (Cicenes et al., 2018). As tyrosine kinase inhibitors (TKIs) are the backbone of systematic therapy for advanced HCC (Chen et al., 2022). It is important for HCC treatment that our drug compounds bind to and inhibit our targets with tyrosine kinase activity. As a result of the literature review, it is seen that these 6 drug compounds are completely new drug candidates for treatment of HCC (Table 12).

As far as we know, for HCC treatment, the predicted drug molecules have never been tested against these transferases using *in silico*, *in vitro*, or *in vivo* assays with respect to HCC. After that, SwissADME (Figure 13, Figure 14, and Table 5-9) and molecular docking (Figure 15, Table 10, and Table 11) were determined for 6 DTIs, which contains 5 different transferases and 6 drug candidates, and HCC approved drugs (lenvatinib, regorafenib, and sorafenib).

The oral bioavailability radar offers a swift evaluation of a compound's drug-likeness by evaluating six physicochemical properties: saturation, lipophilicity, polarity, size, solubility, and flexibility (Adbullahi and Adeniji, 2020). The pink area indicates the optimal range for each property. Lipophilicity (XLOGP3) ranged between -0.7 and +5.0. For size, molecular weights were between 150 and 500 g/mol. Polarity, defined by topological polar surface area (TPSA), ranged from 20 to 130 Å<sup>2</sup>, while solubility (log S) did not exceed 6. In addition, saturation, indicated by the fraction of carbons in sp<sup>3</sup> hybridization, was not less than 0.25, and flexibility was defined by a maximum of 9 rotatable bonds (El-Nashar et al., 2022). Oral bioavailability radar of CHEMBL388978, CHEMBL1615189, CHEMBL328029, CHEMBL1165499, CHEMBL1773581, CHEMBL1773601, and HCC approved drugs (lenvatinib, regorafenib, and sorafenib) were shown in Figure 13. In addition, physicochemical properties of CHEMBL388978, CHEMBL1615189, CHEMBL328029, CHEMBL1165499, CHEMBL1773581, CHEMBL1773601, and HCC approved drugs (lenvatinib, regorafenib, and sorafenib) were shown in Table 5.

Molecular weight (size), XLOGP3 (lipophilicity), fraction csp<sup>3</sup> (saturation), TPSA (polarity), and number of rotatable bonds (flexibility) properties of CHEMBL388978, CHEMBL1615189, CHEMBL328029, CHEMBL1165499, CHEMBL1773581, and CHEMBL1773601 are used in the oral bioavailability radar for determination of the favourable zone. CHEMBL388978, CHEMBL328029, and CHEMBL1165499 are within favourable zone for lipophilicity, size, polarity, solubility, saturation, and

flexibility. CHEMBL1615189 and CHEMBL1773601 are within favourable zone for lipophilicity, size, polarity, solubility, and flexibility except saturation. CHEMBL1773581 is within favourable zone for lipophilicity, size, solubility, and flexibility except saturation and polarity. The analyzed drugs approved for HCC treatment Lenvatinib, regorafenib, and sorafenib meets all criteria except saturation.

In the BOILED Egg diagram, compounds situated within the white elliptical area signify a high likelihood of passive absorption in the gastrointestinal tract. Therefore, compounds fall in the white ellipse region can be absorbed by the human intestinal system. Meanwhile, compounds positioned in the yellow elliptical area, or the “yolk”, indicate a strong chance of penetrating the BBB to reach the central nervous system (CNS). Hence, compounds fall in the yellow ellipse region can pass through the BBB easily (Şahin and Dege, 2022). BOILED Egg diagram of CHEMBL388978, CHEMBL1615189, CHEMBL328029, CHEMBL1165499, CHEMBL1773581, CHEMBL1773601, and HCC approved drugs (lenvatinib, regorafenib, and sorafenib) were shown in Figure 14. CHEMBL388978, CHEMBL328029, and CHEMBL1165499 showed the high BBB penetration and gastrointestinal absorption (GIA) ability according to the BOILED Egg diagram. In addition, when we look at approved drugs, only lenvatinib demonstrated high gastrointestinal absorption.

Five different approaches (iLOGP, XLOGP3, WLOGP, MLOGP, and SILICOS-IT) are used for estimation of lipophilicity (Log Po/w). These methods illustrate alternative approaches to determining how lipophilic (or hydrophobic) a molecule is. Log Po/w measures, such as iLOGP, were determined for n-octanol and water based on the free energies of solvation using the generalized-born and solvent accessible surface area (GB/SA) model by Daina et al. (2014), XLOGP3 is an atomic-based approach with correction factors and a knowledge library developed by Cheng et al. (2007), WLOGP uses a purely atomistic method derived from the fragment system of Wildman and Crippen (1999), MLOGP is a representative topological method that uses a linear relationship with 13 molecular descriptors, as outlined by Moriguchi et al. (1992,1994). Meanwhile, SILICOS-IT combines both approaches, leveraging 27 fragments and 7 topological descriptors. The consensus Log Po/w is the arithmetic mean of the values predicted by the five proposed methods. The averaging process minimizes the possible biases or errors of various approaches, resulting in a more reliable estimate (Daina et al., 2017). Log Po/w is ranged between -0.7 and +5.0 according to the oral bioavailability radar. Log Po/w of CHEMBL388978, CHEMBL1615189, CHEMBL328029, CHEMBL1165499, CHEMBL1773581, CHEMBL1773601, and HCC approved drugs (lenvatinib, regorafenib, and sorafenib) were shown in Table 6. CHEMBL388978, CHEMBL1615189, CHEMBL328029, CHEMBL1165499, CHEMBL1773581, and CHEMBL1773601 are within acceptable range for consensus Log Po/w, indicating favorable characteristics for oral absorption. Lenvatinib is falling within the acceptable range for consensus Log Po/w. Regorafenib and sorafenib are falling within the acceptable range except Log Po/w (WLOGP).

Water solubility (Log S) is ranged between insoluble < -10 < poorly < -6 < moderately < -4 < soluble < -2 very soluble < 0 highly (Henning et al., 2023; Yağlıoğlu et al.,

2022). Log S values of CHEMBL388978, CHEMBL1615189, CHEMBL328029, CHEMBL1165499, CHEMBL1773581, CHEMBL1773601, and HCC approved drugs (lenvatinib, regorafenib, and sorafenib) were shown in Table 7. CHEMBL388978, CHEMBL1165499, and CHEMBL1773581 are within acceptable range for moderately soluble class, while CHEMBL328029 is within acceptable range for soluble class. CHEMBL1615189 and CHEMBL1773601 are within acceptable range for poorly soluble class. Moreover, lenvatinib, regorefenib, and sorafenib are within acceptable range for moderately soluble class.

The druglikeness of the candidate compounds is determined using SwissADME, which uses rule-based filters and the Abbot bioavailability score to identify eligibility based on key pharmacokinetics characteristics. SwissADME uses filtering methods on chemical collections to remove molecules that don't meet the desired pharmacokinetics criteria. This is achieved using five specific rule-based filters created by prominent pharmaceutical corporations [Lipinski (Pfizer), Ghose (Amgen), Veber (GSK), Egan (Pharmacia), and Muegge (Bayer)]. These filters aim to improve the standard of specialized chemical libraries. Furthermore, the Abbott bioavailability score is designed to estimate the chance that a molecule will exhibit a minimum of 10% oral bioavailability in rats or detectable Caco-2 permeability. It forecasts the likelihood of a molecule achieving  $F > 10\%$ , taking into account its primary charge at biological pH in a rat model (Ranjith and Ravikumar, 2019). Druglikeness of the drug candidate compounds and approved drugs were shown in the Table 8. According to druglikeness scores, CHEMBL388978 is within acceptable range for 3 different rule-based filters (Lipinsky, Veber, and Egan) and Abbot bioavailability score. CHEMBL1615189 is within acceptable range for 3 different rule-based filters (Lipinsky, Veber, and Muegge) and Abbot bioavailability score. CHEMBL328029 is within acceptable range for all rule-based filters (Lipinsky, Ghose, Veber, Egan, and Muegge) and Abbot bioavailability score. CHEMBL1165499 is within acceptable range for all rule-based filters except Ghose (Lipinsky, Veber, Egan, and Muegge) and Abbot bioavailability score. CHEMBL1773581 is within acceptable range for 2 different rule-based filters (Lipinsky and Ghose) and Abbot bioavailability score. Lastly, CHEMBL1773601 is within acceptable range for all rule-based filters except Egan (Lipinsky, Ghose, Veber, and Muegge) and Abbot bioavailability score. These assessments show that the compounds have desirable properties for medication development, with various degrees of adherence to recognized pharmacokinetic criteria. When we look at approved drugs, lenvatinib is within acceptable range for all rule-based filters and Abbot bioavailability scor, while regorafenib and sorafenib are within acceptable range for all rule-based filters except Ghose and Egan.

Pan-assay interference compounds (PAINS) have a tendency to nonspecifically interact with multiple biological targets instead of specifically influencing a single desired target. Another tool used in the assessment is Brenk filters. Brenk filters out unwanted functionalities due to potential toxicity or unfavorable pharmacokinetics (Iwaloye et al., 2022). “Lead-likeness” is a strategic guideline for selecting initial points for chemical optimization that have the highest probability of yielding “drug-like” candidates at the conclusion of drug discovery programs. The synthetic

accessibility score of a compound, which measures the ease of synthesis, ranges from 1 (very easy) to 10 (very difficult) (Daina et al., 2017). Medicinal chemistry of the drug candidate compounds and approved drugs were shown in Table 9. According to PAINS filter, all drug candidate compounds and all approved drugs (lenvatinib, regorafenib, and sorafenib) had no alert. Four drug candidate compounds (CHEMBL388978, CHEMBL1165499, CHEMBL1773581 and CHEMBL1773601) and all approved drugs (lenvatinib, regorafenib, and sorafenib) had no alert in Brenk filter. However, two drug candidate compounds (CHEMBL1615189 and CHEMBL328029) had 1 alert in Brenk filter. Another key factor is leadlikeness, which evaluates a compound's overall potential as a starting point for therapeutic development. According to leadlikeness, only CHEMBL328029 had no violation. Lastly, the synthetic accessibility is another parameter, which measures how easily compounds can be produced using standard synthetic methods. Synthetic accessibility of all the drug candidate compounds are close to very easy. However, among the leadlike compounds, CHEMBL328029 is highly accessible, which makes it a viable synthetic option for more research and development. Despite the single alert in the Brenk filter, CHEMBL328029 stands out in the group because to this mix of advantageous features.

Molecular docking is an important tool used to predict the binding behaviors of small molecules to their target proteins, identifying potential sites and affinities crucial for drug development (Gaillard, 2018; Moharana et al., 2023). Here, the docking results provides insights into the molecular interactions specific to HCC for the MDDePred DTIs. "Vina score" mentioned in the Table 10 and Table 11 is an entirely empirical scoring system. It comprises Gaussian steric interaction components, a set repulsion element, piecewise linear hydrophobic and hydrogen-bond interaction components, and an entropy component based on the count of rotatable bonds (Gaillard, 2018). The greater the negative value of the vina score, the greater the Gibbs binding energy for drug-target complexes. This increases the binding potential of drug-target complexes. Contact residues and bonds showed contact amino acids and bond structures between ligands and target proteins. Teal dotted lines illustrate hydrogen bond interactions. Yellow dotted lines show electrostatic interactions, and the hydrophobic interactions are denoted by grey dotted lines (Moharana et al., 2023). As a result, we can clearly see from the molecular docking results (both blind docking and docking for kinase domain) that our drug compounds in the 6 DTIs bind to our transferases (Figure 15, Table 10, and Table 11). In addition, the vina scores for lenvatinib, regorafenib, and sorafenib, which are used to treat advanced HCC, were compared to the vina scores of six small molecules identified in our study. For ALK, CHEMBL1165499 was shown to have a negative vina score (also known as Gibbs binding energy) that was greater than sorafenib and equal to regorafenib. For AKT1, CHEMBL1773601 and CHEMBL1773581 were found to have negative vina scores that were greater than those of any other medication. For FLT3, CHEMBL388978 was shown to have a greater negative vina score than regorafenib and lenvatinib. For PIK3CA, it was discovered that CHEMBL1615189 had a larger negative vina score than lenvatinib. The six small molecules included in our study are potential medication candidates to be employed in the treatment of HCC, according to comparisons with lenvatinib, regorafenib, and

sorafenib, which are utilized in the treatment of advanced HCC. In addition, the molecular docking results for the kinase domains of the targets indicate that the six small molecules identified in this study also exhibited effective binding affinities to the kinase domains of targets beyond those discussed within the scope of this study. This suggests that the six small molecules identified here have the potential to be used as kinase inhibitors in the treatment of HCC (Table S4).

Finally, we performed literature survey about the MDeePred predicted small molecules (Table 12) (Das et al., 2021; Janssen et al., 2018; Jovanović et al., 2018; Tinivella et al., 2022). Tinivella et al. (2022) determined potential biological targets of small molecules with *in silico* repositioning strategies and predicted their interactions using ligand-based similarity predictions and molecular docking analyses. Das et al. (2021) identified new kinases as therapeutic drug targets in their study. They used computational methods to predict the activity of small molecules. Jovanović et al. (2018) in their study, the 3D pharmacophore structure of selective kinase inhibitors was examined using molecular modeling and 3D-QSAR methods. Validated with experimental data, the model showed high reliability in predicting the effectiveness of inhibitors. Janssen et al. (2018) mapped the activity profile of compounds across the kinase family using a ML approach. This model predicted the activities of novel kinase inhibitors.

In the study conducted by Rifaioglu et al. (2021), a performance comparison was made between MDeePred and existing advanced techniques. In this context, it was stated that the MDeePred model exhibited superior performance in many evaluation metrics when compared to prominent methods such as CGKronRLS, DeepDTA, SimBoost and Grid-RF, Grid-DNN, ECFP4-RF and ECFP-RF on the MoleculeNet platform. It was stated that MDeePred outperformed all of these methods in terms of consistency and accuracy in benchmark data sets such as Davis dataset, Filtered Davis dataset and PDBBind Refined dataset. It was emphasized that MDeePred showed strong results, especially at changing biological activity threshold values, in metrics such as concordance index (CI), mean squared error (MSE) and Spearman rank correlation. In addition, it was stated that MDeePred's hybrid deep neural network architecture, which extracts complex representations from target proteins and compounds separately and then combines them, significantly contributes to improved prediction capabilities. This is particularly evident when compared to models based solely on molecular fingerprint-based features. MDeePred was found to be less sensitive to performance degradation at different biological activity thresholds. These results demonstrate that MDeePred's innovative protein characterization approach and deep learning architecture provide a powerful alternative to current state-of-the-art methods for binding affinity prediction and hold significant potential in computational drug discovery.

In addition, in the study conducted by Rifaioglu et al. (2021), an *in vitro* comparative analysis of MDeePred was also performed. In this context, the effects of selected kinase inhibitors on Huh7 and Mahlavu human cancer cell lines were confirmed with the predictions obtained from the MDeePred analysis. In the study, differential gene

expression analyses were performed using well-characterized inhibitors targeting kinase pathways such as staurosporine, rapamycin, NVP-BEZ235 and alsterpaullone. RNA sequencing and subsequent gene expression profiling showed that the predicted binding affinities of MDeePred correlated with the expression changes observed in kinase-related pathways after treatment with these inhibitors. In particular, the study showed that pathways involving protein kinases were significantly changed in response to inhibitors, which supported the predicted mechanism of action of MDeePred. For example, rapamycin treatment targeted the PI3K/Akt/mTOR pathway, leading to upregulation of alternative protein kinases, highlighting possible compensatory mechanisms. Similarly, inhibitors targeting kinases in the cell cycle and MAPK signaling pathway, such as NVP-BEZ235 and alsterpaullone, resulted in downregulation of kinases with low predicted binding affinities. This demonstrated that MDeePred accurately identified the kinases most affected by specific inhibitors, consistent with the observed gene expression profile changes.

## CHAPTER 5

### CONCLUSION

Hepatocellular carcinoma (HCC) is the most common primary liver cancer with a high mortality rate due to limited treatment options. Although current systemic drug treatments slightly increase patients' survival rates, these treatments generally extend lifespan by only a few months and are insufficient to improve patients' quality of life. The development of new small molecule chemotherapeutics is quite time-consuming and costly, so alternative strategies are of great importance. In this context, the drug repurposing approach emerges as an important strategy in the rapid and effective identification and implementation of new treatment options for this deadly disease.

In this study, we aimed to identify potential drug candidates for HCC treatment by repurposing existing compounds using a machine learning (ML) tool called MDDeePred. The open target platform, UniProt, ChEMBL, and ExPasy databases were used to create a dataset for MDDeePred to predict drug-target interactions (DTIs). The physicochemical properties, lipophilicity, water solubility, drug-likeness and medicinal chemistry properties of the drug candidates were meticulously determined and curated.

Enrichment analyzes of DTIs were performed, resulting in 6 out of 380 DTIs identified by MDDeePred being selected for further analysis. The vast majority of these drug candidates fall within conventional ranges in terms of drug properties and demonstrate target docking capabilities. The findings reveal the binding efficiency of selected drug compounds to identified targets associated with HCC. These results suggest that the drug repurposing strategy is a potentially promising avenue for treating HCC.

The current therapy options for HCC differ based on the illness stage, tumor size, the patient's overall health, and liver function. However, the most commonly approved treatments include surgical resection, liver transplantation, local ablative therapies, TACE, molecular targeted medicines, and immunotherapy. Our research focuses on molecular targeted medicines, especially TKIs such as sorafenib and lenvatinib, which are authorized therapy for advanced HCC. These small molecule medicines decrease tumor development and angiogenesis. Our research identified six small compounds that interact with genes that have kinase activity, including FGFR1, ALK, and FLT3 proteins having tyrosine kinase activity. These results imply that the six small compounds might be used as kinase or TKIs in the treatment of HCC. After *in vitro* and *in vivo* testing, these potential drug candidates will be ready for clinical usage.

In conclusion, this study identified potential drug candidates that can be further evaluated experimentally for the treatment of HCC using the ML-based *in silico* MDeePred method. Additionally, this study highlights that the MDeePred deep learning tool can play an important role in drug repurposing studies in cancer treatment. In other words, we showed that ML techniques can be applied to drug repurposing in HCC to find new therapeutic agents with very drug-like qualities that are comparable to those of approved HCC medications. MDeePred's high accuracy rates and comprehensive data processing capacity accelerate the drug discovery process and increase the potential to develop more effective treatment options. This approach aims to contribute to the development of new therapeutic strategies for HCC and other types of cancer, providing better quality of life and long-term survival rates for patients.

## CURRICULUM VITAE

Surname, Name : Başer, Tuğçe  
Nationality : T.C.  
Marital Status : Single

### **EDUCATIONAL BACKGROUND:**

**Ph.D.** : Middle East Technical University, Department of Medical Informatics (ANKARA) (2016-) 3.88/4.00  
**Thesis Title** : "Application of Machine Learning Methods in Drug Development for Liver Cancer"  
**Advisor** : Dr. Öğr. Üyesi Burçak OTLU SARITAŞ  
**Co-advisor** : Prof. Dr. Rengül ÇETİN ATALAY

**Master's Degree** : Middle East Technical University, Graduate School of Natural and Applied Sciences, Department of Biology (2010-2013) 3.64/4.00

**Thesis Title** : "Determination of Lipid Profiles in Genetic Obese Mice Adipose Tissues Using High-Performance Liquid Chromatography"

**Advisor** : Prof. Dr. Feride SEVERCAN

**Undergraduate** : Middle East Technical University, Faculty of Science, Department of Biology (ANKARA) (2005-2010) 2.85/4.00

**High School** : M.E.V. Private Ankara Science High School (ANKARA) (2002-2005) 5.00/5.00

### **PROFESSIONAL EXPERIENCE:**

**October 2022 - Present:** TÜBİTAK ARGES Senior Expert in Scientific Programs

**September 2018 - October 2022:** TÜBİTAK ARGES Expert in Scientific Programs

**February 2016 - September 2018:** TÜBİTAK ARGES Assistant Expert in Scientific Programs

**December 2014 - February 2016:** TÜBİTAK KBAG Assistant Expert in Scientific Programs

**LANGUAGE PROFICIENCY:**

Turkish (Native), English (Intermediate)

**COMPUTER SKILLS:**

Microsoft Word, Excel, PowerPoint, Windows 11

**OTHER INFORMATION**

**INTERNSHIPS:**

**September 2010 - September 2013:** Middle East Technical University  
Molecular Biophysics Laboratory  
TÜBİTAK Project  
3 years, Master's Student  
Supervisor: Prof. Dr. Feride SEVERCAN

**July 2009 - August 2009:** Hacettepe Hospital  
Department of Basic Oncology  
1.5 months, Summer Internship (mandatory)

**2008-2010:** Cancer, Molecular Biology, and Drug Resistance  
Cancer Laboratory at Middle East Technical University  
TÜBİTAK Project  
Volunteer Project Assistant  
Supervisor: Prof. Dr. Ufuk GÜNDÜZ

**ACHIEVEMENTS:**

Middle East Technical University High Honor Certificate for the Spring 2010 Semester

Three Middle East Technical University Honor Certificates between Fall 2008 and Spring 2009

First Place Certificate at M.E.V. Private Ankara Science High School (2005)

## **RESEARCH PROJECTS:**

TÜBİTAK, Characterization of Structure, Function, and Content of Different Adipose Tissues in Inbred Obese Mouse Models, Project Code: 110S23, Project Supervisor: Prof. Dr. Feride SEVERCAN, Scholar: Tuğçe BAŞER (2011-2012)

Middle East Technical University Scientific Research Projects Unit, Targeting Cancer Cells with Doxorubicin-Loaded Nanoparticles, Project Supervisor: Prof. Dr. Ufuk GÜNDÜZ (2008-2010)

TÜBİTAK, Synthesis of Idarubicin-Loaded Magnetic Nanoparticles and Application to MCF-7 Breast Cancer Cell Line, Project Code: 109T949, Project Supervisor: Prof. Dr. Ufuk GÜNDÜZ (2009)

## **TRAINING:**

Ministry of Industry and Technology, Remote Education Platform Crisis Management Training, In-Service Training (Online) (16 December 2021)

Ministry of Industry and Technology, Remote Education Platform Effective Presentation Techniques, In-Service Training (Online) (20 October 2021)

BTK Academy, Introduction to Big Data Training (Online) (20 October 2021)

BTK Academy, Written Communication Techniques Training (Online) (19 October 2021)

Ministry of Industry and Technology, Remote Education Platform Importance of Motivation for Employee Productivity, In-Service Training (Online) (20 August 2021)

Ministry of Industry and Technology, Remote Education Platform Human Rights, In-Service Training (Online) (26 July 2021)

Ministry of Industry and Technology, Remote Education Platform Archival Legislation and Archival Awareness, In-Service Training (Online) (14 July 2021)

Ministry of Industry and Technology, Remote Education Platform Ethics in the Framework of Human Rights, In-Service Training (Online) (12 July 2021)

Ministry of Industry and Technology, Remote Education Platform Good Governance Principles in the Context of the Ombudsman Institution, In-Service Training (Online) (12 July 2021)

Ministry of Industry and Technology, Remote Education Platform Gender Equality in the Workplace Based on Human Rights, In-Service Training (Online) (12 July 2021)

Ministry of Industry and Technology, Remote Education Platform Risk Taking / Problem Solving and Decision Making / Result Orientation, In-Service Training (Online) (1 April 2021)

Ministry of Industry and Technology, Remote Education Platform Awareness Training on the Power of Communication / Zafer Kiraz, In-Service Training (Online) (1 March 2021)

Ministry of Industry and Technology, Remote Education Platform Official Correspondence Procedures and Principles, Mandatory Training (Online) (22 February 2021)

Ministry of Industry and Technology, Remote Education Platform Oratory and Effective Presentation Training, In-Service Training (Online) (16 February 2021)

Ministry of Industry and Technology, Remote Education Platform Body Language and Communication Training, In-Service Training (Online) (16 February 2021)

Ministry of Industry and Technology, Remote Education Platform Public Ethics and Ethical Behavior Principles for Public Officials, Mandatory Training (Online) (31 January 2021)

Ministry of Industry and Technology, Remote Education Platform Diction, Mandatory Training (Online) (30 January 2021)

Ministry of Industry and Technology, Remote Education Platform Importance of Content in Communication, Mandatory Training (Online) (29 January 2021)

Ministry of Industry and Technology, Remote Education Platform Public Speaking, Mandatory Training (Online) (29 January 2021)

Ministry of Industry and Technology, Remote Education Platform Common Postural Problems and Office Exercises for Office Workers, Mandatory Training (Online) (5 November 2020)

Ministry of Industry and Technology, Remote Education Platform Applied Excel Training, Mandatory Training (Online) (15 October 2020)

TÜBİTAK, Basic Photography Training (ANKARA) (3 October 2017 - 21 November 2017)

Middle East Technical University Basic First Aid Training (26.02.2010-28.05.2010)

## **CERTIFICATES:**

Ministry of Health, First Aid Certificate (2021)

Yaşamartı, Participation Certificate at Yaşamartı Personal Development Summit: "Don't Worry About Everything in Life" by Ozanser UĞURLU (ANKARA) (22 October 2017)

Yaşamartı, Participation Certificate at Yaşamartı Personal Development Summit: "The Power of Knowledge" by Prof. Dr. İlber ORTAYLI (ANKARA) (22 October 2017)

Yaşamartı, Participation Certificate at Yaşamartı Personal Development Summit: "Simplicity in Communication: Effective Listening & Correct Listening & Correct Interpretation" by Deniz BAYRAMOĞLU (ANKARA) (22 October 2017)

Yaşamartı, Participation Certificate at Yaşamartı Personal Development Summit: "The Future of Business Life" by Erdem AKSAKAL (ANKARA) (22 October 2017)

Gazi University, Faculty of Education, Department of Biology Teaching, Pedagogical Formation Certificate (ANKARA) (2012-2013)

Middle East Technical University Basic First Aid Certificate (2010)

## **EVENTS:**

TEDxMETU, "Great Illusions" (ANKARA) (3 December 2017)

## **SOCIAL CLUBS:**

METU Bio-Gen Society (2005-2010)

M.E.V. Private Ankara Science High School Volleyball Team (2002-2005)

M.E.V. Private Ankara Primary School Volleyball Team (1998-2002)
