# ABSTRACT <br> FLEXIBLE ASSEMBLY LINE DESIGN PROBLEM WITH FIXED NUMBER OF WORKSTATIONS 

Barutçuoğlu, Şirin<br>M.S. Department of Industrial Engineering<br>Supervisor: Prof. Dr. Meral Azizoğlu

July 2009, 70 pages

In this thesis, we study a Flexible Assembly Line Design problem. We assume the task times and equipment costs are correlated in the sense that for all tasks the cheaper equipment gives no smaller task time. Given the cycle time and number of workstations we aim to find the assignment of tasks and equipments to the workstations that minimizes the total equipment cost. We study a special case of the problem with identical task times. For the general case, we develop a branch and bound algorithm that uses powerful lower bounds and reduction mechanisms. We test the performance of our branch and bound algorithm on randomly generated test problems. The results of our experiments have revealed that we are able to solve large-sized problem instances in reasonable times.

Keywords: Flexible Assembly Lines, Assembly Line Balancing, Branch and Bound Algorithm

Bu tezde Esnek Montaj Hattı Tasarımı problemini ele aldık. İş süreleri ve ekipman maliyetlerinin bağlantılı olduğu, işlerin pahalı ekipmanlarla, daha ucuz ekipmanlarla yapıldığından daha uzun sürede yapılamayacağı varsayıldı. Çevrim zamanı ve iş istasyonu sayısı verilmiş iken, işlerin ve ekipmanların iş istasyonlarına toplam ekipman maliyetini en aza indirecek şekilde atanması hedeflendi. Öncelikle problemin özdeş işleri varsayan özel durumu çalışıldı. Genel problem için, güçlü alt limitler ve eleme mekanizmaları kullanan bir dalsınır algoritması geliştirildi. Dal-sınır algoritmasının performansı rassal olarak yaratılan test problemleri üzerinde değerlendirildi. Deneysel sonuçlar, büyük ölçekli problemlerin önerilen algoritma ile makul sürelerde çözülebildiğini göstermiştir.

Anahtar Kelimeler: Esnek Montaj Hatları, Montaj Hattı Dengeleme, Dal-Sınır Algoritmasi

To my mom

## ACKNOWLEDGMENTS

First of all, I would like to express my gratitude to my supervisor, Prof. Meral Azizoğlu. She has been more than a supervisor for me. She was always very hearty and friendly as a sister. She did her best to encourage and guide me throughout this study. I would like to underline that she is an excellent person and very important for me. I am very happy that we will be able to work together in the coming years.

I owe thanks to Prof. N. Evin Özdemirel for her sincere support at my hard times. In addition, I would like to thank Assoc. Prof. Canan Sepil for her valuable advices and smiling face. I would also like to thank my examining committee members Prof. Ömer Kırca, Asst. Prof. Banu Yüksel Özkaya, Assoc. Prof. Canan Sepil and Asst. Prof. İsmail Serdar Bakal for their positive attitude and contributions to this study.

I would like to thank my friends Banu Lokman, Büşra Atamer, Melih Çelik and Tülin İnkaya for their warm interest and sympathy. Also, I would also like to thank all my professors for their important contributions. It is a great honor to be a part of METU-IE.

I am grateful to my parents Gülnaz and Şuaip Öztürk for their endless care, support and altruism. I am proud of being their daughter. I would like to expess my love for my brother Göksel Öztürk. I feel very fortunate to have such a sweet brother. I would also like to thank Zeynep and Ömer Barutçuoğlu for their heartiness and goodwill.

My love and my husband, Aras gave a novel touch to my life. I would like to send my deepest thanks to him for his endless love, patience and every thing he added to my life.

## CHAPTER 1

## INTRODUCTION

An assembly line is a production system, in which different parts are assembled on a product that flows through a sequence of workstations. The workstations are usually connected by a continuous material handling system and a set of assembly tasks is assigned to each workstation. These tasks are indivisible and performed according to some pre-specified restrictions. These restrictions are generally of two types: precedence relations and demand satisfaction. The precedence relations define the technological order such that some tasks can start only after the completion of some other tasks. The demand satisfaction constraint forces the assembly line to deliver a product at the end of each pre-specified period. This period, i.e., the time between two successive product completions, is referred to as cycle time. The cycle time is the reciprocal of the production rate, hence minimizing the cycle time is equivalent to maximizing the production rate.

In Operations Research literature, the decision problem of assigning the assembly tasks to the workstations with respect to some pre-defined objective is called Assembly Line Balancing (ALB) problem. In the literature, basically two types of ALB problems, namely Type 1 and Type 2 ALB problems, are studied. In Type 1 problems, the aim is to minimize the number of workstations given a pre-determined cycle time (hence production rate), whereas in Type 2 problems, the aim is to minimize cycle time (hence maximize production rate) given a fixed number of workstations.

Type 1 problems are usually observed when a new assembly line is to be designed. The purpose is to satisfy the demand with the minimum number of workstations. On the other hand, when the organization wants to produce the
maximum number of products without investing on new machines or expanding the existing ones, Type 2 problems gain significant importance.

In assembly lines, workstations are the places where the resources are assigned and consumed. In traditional assembly lines there is a single resource in each workstation and the resources are identical over all workstations. The single resource is usually represented by a worker together with his/her equipment. On the other hand, flexible assembly lines consider various resources as alternatives for performing each task. The resources may be labor (of different skill) or machinery (of different speed). The resources are usually represented by pieces of equipments where each equipment has a specified cost of assignment and a specified speed to perform each task.

Flexible Assembly Lines are gaining significant value due to their practical importance and theoretical challenge. In practice, to remain competitive in the market, the companies should use Flexible Assembly Lines to achieve high efficiency and respond ever changing customer demands. The automated equipments such as robots or Computer Numerically Controlled machines can offer shorter task times as well as more complex and precise assembly tasks.

Theoretically, the analysis of the Flexible Assembly Lines is challenging due to the complexity brought by equipment alternatives. The alternatives add selection decisions to the task assignment decisions of the traditional lines. The equipment selection decisions have long term impacts as an equipment is usually purchased at high prices. The associated problems are referred to as Flexible Assembly Line Design problems and they usually aim to minimize total equipment cost.

Despite its practical and theoretical importance, the research on Flexible Assembly Line Design problems is quite scarce. The existing literature assumes a limit on the cycle time, but not on the number of workstations. Their
objective is to minimize the total equipment cost, which is equivalent to minimizing the number of workstations when all equipment costs are equal.

In this study, we consider a Flexible Assembly Line Design problem with specified cycle time and fixed number of workstations. That is, we assume that there is a target production rate and the workstations of the line are already located. In such an environment, we aim to minimize the total equipment cost. Moreover, we assume all the task times either decrease or remain same when more advanced, hence expensive, equipment is used. For example, a Computer Numerically Controlled machine is likely to perform the tasks faster than a conventional machine and it is much more expensive.

The rest of thesis is organized as follows: In Chapter 2, we define our problem, introduce the notation and give the mathematical model. The chapter reviews the related literature and introduces a special case with identical task times. Chapter 3 presents our solution approach together with reduction and bounding mechanisms. In Chapter 4, we give the results of our computational experiment. We conclude in Chapter 5 by pointing out main conclusions and suggestions for future research.

## CHAPTER 2

## THE PROBLEM DEFINITION

In this chapter we first define our problem and give the mathematical formulation of the problem with general task times. We then introduce and give the mathematical model of the problem in which task times are correlated with the equipment costs. Next, we introduce a special case of the problem with identical task times. Finally, we give a brief review of the related literature.

### 2.1. PROBLEM STATEMENT

We consider a single product Assembly Line Design Problem with equipment decisions, specified minimum production rate and a fixed number of workstations. Our aim is to minimize total equipment cost over all workstations.

We suppose the processing times of the tasks may differ according to their equipments. We assume that each task requires a single equipment and all equipment alternatives are capable of performing all tasks.

### 2.1.1. THE GENERAL TASK TIMES MODEL

In this section, we consider the Flexible Assembly Line Design problem with general task times. We state our assumptions, give the notation and provide the mixed integer programming model.

Our assumptions are;

- A single product is assembled on the line.
- The tasks are indivisible.
- There is a predetermined upper limit on the number of workstations.
- The cycle time of the line is given.
- All parameters, i.e., task times, equipment costs, precedence structure, cycle time are known with certainty and are not subject to change, i.e., the system is deterministic and static.
- The task times differ with respect to the equipments. We use the terms task times and processing times interchangeably throughout the thesis.
- The task times do not vary according to the workstations and/or the precedence relations.
- The set of equipment types is given and each equipment type has a specific cost. This unit cost includes purchasing and all operational costs. We use the terms equipment types and equipments interchangeably throughout the thesis.
- The equipment costs do not change with respect to tasks.
- There is no set up time between different tasks.
- All tasks can be performed in all workstations and all equipment types can be assigned to all workstations.
- The number of equipments that can be assigned to a workstation is limited.
- The number of tasks that can be assigned to a workstation is not limited.

## Sets:

$i$ : the set of tasks to be completed , $i=1,2, \ldots, N$
$l$ : the set of equipments (or tools) to perform the tasks, $l=1,2, \ldots, L$
$k$ : the set of workstations that include the equipments , $k=1,2, \ldots, K$

## Parameters:

$C T$ : cycle time, i.e., maximum time allowed in a workstation
$K$ : number of workstations on the line, i.e., maximum number of workstations that can be used $t_{i l}$ : task time of task i when performed with equipment $l$
$E C_{l}$ : cost of equipment $l$
$C P_{k}$ : equipment capacity of workstation $k$
$P=\{(a, b) \mid a$ immediately precedes $b\}$

## Decision Variables:

$y_{l k}=\left\{\begin{array}{l}1, \text { if equipment } l \text { is assigned on workstation } k \\ 0, \text { otherwise }\end{array}\right.$
$x_{i l k}=\left\{\begin{array}{l}1, \text { if task i is assigned to equipment } l \text { and workstation } k \\ 0, \text { otherwise }\end{array}\right.$

## Mathematical Model:

The objective function minimizes the total equipment cost.
$\operatorname{Min} \sum_{l=1}^{L} \sum_{k=1}^{K} E C_{l} y_{l k}$

Constraint set (1) ensures that each task will be assigned to one equipment type and one workstation.

$$
\begin{equation*}
\sum_{l=1}^{L} \sum_{k=1}^{K} x_{i l k}=1 \tag{1}
\end{equation*}
$$

$$
\forall i
$$

Constraint set (2) makes sure that if a task is assigned to a workstation, its equipment should also be assigned to that workstation.

$$
\begin{equation*}
x_{i l k} \leq y_{l k} \quad \forall i, l, k \tag{2}
\end{equation*}
$$

Constraint set (3) makes sure that the minimum required production rate is satisfied, that is the cycle time limit is not exceeded.

$$
\begin{equation*}
\sum_{l=1}^{L} \sum_{i=1}^{N} t_{i l} x_{i l k} \leq C T \quad \forall k \tag{3}
\end{equation*}
$$

Constraint set (4), prevents precedence violation. It guarantees that if task $a$ immediately precedes task $b$ then task $a$ cannot be assigned to a later workstation than task $b$.
$\sum_{l=1}^{L} \sum_{k=1}^{K} k x_{a l k} \leq \sum_{l=1}^{L} \sum_{k=1}^{K} k x_{b l k} \quad \forall(a, b)$ such that $a$ immediately precedes $b$

Constraint set (5) limits the number of equipments assigned to a workstation.

$$
\begin{equation*}
\sum_{l=l}^{L} y_{l k} \leq C P_{k} \quad \forall k \tag{5}
\end{equation*}
$$

Constraint sets (6) - (7) are the binary assignment constraints.

$$
\begin{array}{ll}
x_{i l k} \in\{0,1\} & \forall i, l, k \\
y_{l k} \in\{0,1\} & \forall l, k \tag{7}
\end{array}
$$

### 2.1.2. THE CORRELATED TASK TIMES MODEL

In this section, we assume the task times and equipment costs are correlated in the sense that for all tasks the cheaper equipment gives no smaller task time. Hence we consider a special case of the model stated in Section 2.1.1. The motivation behind this assumption is the fact that usually more advanced and faster equipments are more expensive. For example, CNC machines are more expensive than the conventional ones and they usually perform the tasks quicker, at least no slower.

According to our assumption, for two equipments $a$ and $b, E C_{a}>E C_{b}$, implies $t_{i a} \leq t_{i b}$ for all tasks $i$. We hereafter assume that the equipments are indexed such that $E C_{1}>E C_{2}>\ldots . .>E C_{L}$, i.e., the first equipment is the most expensive, hence the fastest, equipment.

We now state an important theorem for all optimal solutions.

Theorem 1: In all optimal solutions, at most one equipment is assigned to each workstation.

Proof: Assume the condition stated in above property does not hold and there are $R$ equipments assigned to a workstation, say workstation $k$. The total cost of the equipments on workstation $k, Z_{k}=\sum_{l \in S_{k}} E C_{l}$ where $S_{k}$ is the set of equipments assigned to workstation $k$. Assume equipment $r$ is the most expensive equipment in $S_{k .}$ As $E C_{r}>E C_{s}$ implies $t_{i r} \leq t_{i s}$, it is always possible to process all tasks with equipment $r$ and freed the other $R-1$ equipments. This leads to an equipment cost $Z_{k}{ }^{\prime}=E C_{r}$. As $Z_{k}{ }^{\prime}<Z_{k}$, the solution that contradicts with our property cannot be optimal.

Theorem 1 implies that, constraint set (5) is always satisfied as long as the equipment capacity of the workstations is greater than or equal to 1 . Hence, the right hand side of constraint set (5) can be set to 1 . This setting reduces the solution space, thus leads to a stronger formulation. Moreover constraint sets (2) and (3) can be replaced by a single constraint set since at most one equipment exists in each workstation. The resulting constraint becomes;

$$
\begin{equation*}
\sum_{i=1}^{N} t_{i l} x_{i l k} \leq C T \cdot y_{l k} \quad \forall l, k \tag{8}
\end{equation*}
$$

With these modifications, below is the statement of the model with correlated task times.
$\operatorname{Min} \sum_{l=1}^{L} \sum_{k=1}^{K} E C_{l} y_{l k}$
s.to
$\sum_{l=1}^{L} \sum_{k=1}^{K} x_{i l k}=1 \quad \forall i$
$\sum_{i=1}^{N} t_{i l} x_{i l k} \leq C T \cdot y_{l k} \quad \forall l, k$
$\sum_{l=1}^{L} \sum_{k=1}^{K} k x_{a l k} \leq \sum_{l=1}^{L} \sum_{k=1}^{K} k x_{b l k} \quad \forall(a, b)$ such that a precedes b
$\sum_{l=1}^{L} y_{l k} \leq 1 \quad \forall k$
$x_{i l k} \in\{0,1\} \quad \forall i, l, k$
$y_{l k} \in\{0,1\} \quad \forall l, k$

We hereafter refer to our Flexible Assembly Line Design problem with correlated times and costs as P.

### 2.1.3. AN EXAMPLE PROBLEM

In this section we illustrate a feasible and an optimal solution of P via an 11 tasks and 5 equipments example. We assume the line has four workstations and the required cycle time is 30 time units. The precedence relations between tasks are shown in the following figure.

Figure 2.1 Precedence graph of the example problem

The task times depending on the equipment used and equipment costs are given in Table 2.1.

Table 2.1 Task Times and Equipment Costs of the Example Problem

| Tasks | Equipments |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 7 | 10 | 10 | 13 | 13 |
| 2 | 6 | 6 | 8 | 12 | 12 |
| 3 | 6 | 6 | 7 | 8 | 10 |
| 4 | 8 | 9 | 10 | 11 | 12 |
| 5 | 6 | 8 | 8 | 9 | 13 |
| 6 | 6 | 8 | 10 | 12 | 12 |
| 7 | 6 | 7 | 7 | 7 | 10 |
| 8 | 8 | 9 | 9 | 10 | 13 |
| 9 | 8 | 11 | 12 | 12 | 13 |
| 10 | 8 | 9 | 9 | 11 | 13 |
| 11 | 6 | 6 | 6 | 9 | 12 |
| Equipment Costs | 400 | 350 | 300 | 250 | 200 |

One feasible solution to P is shown in Figure 2.2 .

Figure 2.2 A feasible solution of the example problem

Total equipment cost $=E C_{1}+E C_{1}+E C_{3}=400+400+300=1100$.

The cycle time constraints are satisfied. Specifically,
$t_{11}+t_{21}+t_{31}+t_{41}=7+6+6+8=27 \leq 30$,
$t_{51}+t_{61}+t_{71}+t_{81}=6+6+6+8=26 \leq 30$ and
$t_{93}+t_{10,3}+t_{11,3}=12+9+6=27 \leq 30$.

The assignments are also precedence feasible.

The following configuration (depicted in Figure 2.3) indicates an optimal solution for P . The solution uses all four workstations.

Figure 2.3 An optimal solution of the example problem

The solution is feasible as
$t_{25}+t_{45}=12+12=24 \leq 30$,
$t_{13}+t_{33}+t_{63}=10+7+10=27 \leq 30$,
$t_{54}+t_{74}+t_{94}=9+7+12=28 \leq 30$,
$t_{84}+t_{10,4}+t_{11,4}=10+11+9=30 \leq 30$ and the precedence relations hold.

It is optimal with total equipment cost of $E C_{5}+E C_{3}+E C_{4}+E C_{4}$

$$
=200+300+250+250=1000 .
$$

### 2.2. COMPLEXITY OF THE PROBLEM

In this section we show that P is strongly NP-hard through a reduction to the Type 1 ALB problem. Theorem 2 states this result formally.

Theorem 2: P is NP-hard in the strong sense.

Proof: Assume a special case of P , in which $t_{i l}=t_{i}$ for all equipment types $l$, i.e., the task times are independent of the equipment types. Moreover, assume that $E C_{i}=E C$, i.e., the equipments are identical. This special case of the problem reduces to the minimization of the number of workstations, i.e., classical Type 1 assembly line balancing problem. If the resulting optimal number of workstations is greater than the available number of workstations, then P is infeasible, otherwise, the limit on the number of workstations is not restrictive. The Type 1 assembly line balancing problem is strongly NP-hard, so is our problem with arbitrary task times and costs.(see Baybars (1986))

### 2.3. A SPECIAL CASE - IDENTICAL TASK TIMES

Suppose $t_{i l}=t_{l}$ for all tasks $i$ and for all equipment types $l$, i.e., tasks are identical in terms of task times, where $t_{l}$ is time required for equipment type $l$ to perform any task.

In such a case, $n_{l}$, maximum number of tasks an equipment type $l$ can perform in a workstation can be defined as $n_{l}=\left\lfloor\frac{C T}{t_{l}}\right\rfloor$.

Using this definition, we formulate a special case of P , which we call Assembly Line Design Problem with Identical Tasks and Correlated Task Times ( we refer to this special case as PI ), as follows.

## Parameters:

$K$ : maximum number of workstations
$E C_{l}$ : cost of equipment $l$
$N$ : number of tasks
$n_{l}$ : maximum number of tasks an equipment type $l$ can perform in a workstation

## Decision Variables:

$y_{l}$ : number of equipments that will be used from equipment type $l$

## Mathematical Model:

$\operatorname{Min} \sum_{l=1}^{L} E C_{l} y_{l}$
$\sum_{l=1}^{L} n_{l} \cdot y_{l} \geq N$
$\sum_{l=1}^{L} y_{l} \leq K$
$y_{l}$ integer $\quad \forall l$

Constraint (10) makes sure that all tasks are performed. Constraint (11) ensures there are at most $K$ equipments, since there will be at most one equipment in a workstation (see Theorem 1).

Precedence constraints are not included as we can always define a feasible sequence according to the precedence relations, after finding the optimal solution.

Note that the model has only two constraints in this formulation. So, the optimal LP relaxation of the problem has at most two positive variables. This also means that there can be at most two fractional variables, in the optimal LP relaxed solution.

Below we state some properties of the optimal LP relaxation of PI.

P1) In the optimal solution constraint (10) will be satisfied as strict equality due to the positive objective function coefficients of $y_{l}$. Thus, $\sum_{l=1}^{L} n_{l} \cdot y_{l}=N$.

Note that, $\frac{E C_{l}}{n_{l}}$ gives the cost of performing one task with equipment type $l$. Accordingly, the equipment giving $\operatorname{Min}_{l}\left\{\frac{E C_{l}}{n_{l}}\right\}$ will be favored in the optimal solution. We let $a$ be the equipment with $\operatorname{Min}_{l}\left\{\frac{E C_{l}}{n_{l}}\right\}$.

P2) If $\frac{N}{n_{a}} \leq K$ then $y_{a}=\frac{N}{n_{a}}$ and $y_{i}=0$ for all $i$ other than $a$, in the optimal solution.

P3) If $\frac{N}{n_{a}}>K$, then constraint (11) will be satisfied with strict equality in the optimal solution. Thus, $\sum_{l=1}^{L} y_{l}=K$.

P4) Let $b$ be the equipment type giving $\operatorname{Min}_{l \in B}\left\{\frac{E C_{l}}{n_{l}}\right\}$ where $B=\left\{l \left\lvert\, \frac{N}{n_{l}} \leq K\right.\right\}$, i.e., the set of equipment types that can give a feasible solution alone. $y_{b}>0$ in the optimal solution.

Using the results of P2, P3 and P4, we find the optimal relaxed solution with at most $L-1$ trials (number of $b-i$ pairs). We further reduce the number of trials by P5 and P6.

P5) An equipment type $l \in B$ is eliminated if $\frac{E C_{l}}{n_{l}}>\frac{E C_{b}}{n_{b}}$. (As $b$ exists in the optimal solution together with an equipment having smaller $\frac{E C_{l}}{n_{l}}$ value to reach a smaller objective function value than $E C_{b} \cdot \frac{N}{n_{b}}$ )

P6) If $n_{c}=n_{d}$ and $E C_{c} \geq E C_{d}$ for equipment types $c$ and $d$ then $y_{c}$ cannot take a positive value in the optimal solution.

We now discuss the way that we find the optimal relaxed solution. Using P4 we know, $b$, one of the two equipments that takes positive value in the optimal solution. From P1 and P3, we have the following two equations with two unknowns. P3 implies that it is not feasible to use only the equipment with $\operatorname{Min}_{l}\left\{\frac{E C_{l}}{n_{l}}\right\}$.

$$
\begin{aligned}
& n_{i} \cdot y_{i}+n_{b} \cdot y_{b}=N \\
& y_{i}+y_{b}=K
\end{aligned}
$$

where $i$ is the other equipment that may take positive value. The simultaneous solution of the two equalities yields the following solution values.
$y_{b}=\frac{N-n_{i} \cdot K}{n_{b}-n_{i}}$ and $y_{i}=\frac{n_{b} \cdot K-N}{n_{b}-n_{i}}$.

The objective function value with equipments $b$ and $i, O_{b i}$, is found as,

$$
O_{b i}=E C_{b} \frac{N-n_{i} \cdot K}{n_{b}-n_{i}}+E C_{i} \frac{n_{b} \cdot K-N}{n_{b}-n_{i}} .
$$

Hence the optimal objective function value of the relaxed problem is

$$
z=\operatorname{Min}_{i \in \bar{E}}\left\{\left(E C_{b} \frac{N-n_{i} \cdot K}{n_{b}-n_{i}}+E C_{i} \frac{n_{b} \cdot K-N}{n_{b}-n_{i}}\right), E C_{b} \frac{N}{n_{b}}\right\}
$$

where $\bar{E}$ is the set of the remaining equipments.

If $\mathrm{z}=E C_{b} \frac{N}{n_{b}}$, i.e., a single equipment is used, then

$$
y_{b}^{*}=\frac{N}{n_{b}}, y_{i}^{*}=0 \text { for all } i \neq b
$$

Otherwise, i.e, if equipments $b$ and $i$ are used together,

$$
y_{b}^{*}=\frac{N-n_{i} \cdot K}{n_{b}-n_{i}}, \quad y_{i}^{*}=\frac{n_{b} \cdot K-N}{n_{b}-n_{i}}, \quad y_{j}^{*}=0 \text { for all } j \neq b, i .
$$

We now focus on some cases where we find optimal integer solution for the problem. These cases are discussed below.

Case 1. If P6 leaves one equipment, say equipment $b$, then the optimal cost is $z=E C_{b}\left\lceil\frac{N}{n_{b}}\right\rceil$

Case 2. If P6 leaves two equipments, say equipment $a$ and $b$ such that $E C_{a}<E C_{b}$. Then $n_{a}<n_{b}$.

Note that $\left\lceil\frac{N}{n_{a}}\right\rceil$ is a valid upper bound on the number of workstations. Hence, we update $K=\operatorname{Min}\left\{K,\left\lceil\frac{N}{n_{a}}\right\rceil\right\}$.

Let $r \in[1, K]$ be the number of equipments of type $a$. So, the number of equipments of type $b$ is $\left\lceil\frac{N-n_{a} \cdot r}{n_{b}}\right\rceil$ to perform all $N$ tasks on the line. Then $r+\left\lceil\frac{N-n_{a} \cdot r}{n_{b}}\right\rceil$ should not exceed the available number of workstations.

Hence, the optimal number of equipments of types $a$ and $b$ and optimal objective value can be expressed with the following expressions.

$$
\begin{aligned}
& y_{b}^{*}=\left\lceil\frac{N-n_{a} \cdot y_{a}^{*}}{n_{b}}\right\rceil \\
& z=\operatorname{Min}_{0 \leq r \leq K}\left\{\left.E C_{a} \cdot r+E C_{b} \cdot\left\lceil\frac{N-n_{a} \cdot r}{n_{b}}\right\rceil \right\rvert\, r+\left\lceil\frac{N-n_{a} \cdot r}{n_{b}}\right\rceil \leq K\right\}
\end{aligned}
$$

### 2.4. LITERATURE REVIEW

In this section we give a literature review on Type 2 Assembly Line Balancing (ALB) problems in general and Assembly Line Design problems with equipment decisions in particular.

Although Assembly Line Balancing (ALB) literature is very rich, the research on Flexible Assembly Line Design problem is quite scarce.

Baybars (1986) surveys Type 1 and Type 2 ALB problems. He describes modifications and generalizations of the problems in chronological order. He gives different formulations and proposes exact solution approaches.

Some noteworthy Type 2 ALB problems are due Hackman et al. (1989), Uğurdağ et al. (1997), Rekiek et al. (1999) and Liu et al. (2005). Hackman et al. (1989) propose a heuristic for Type 1 ALB problem. They develop a branch
and bound algorithm that uses the heuristic bounding procedure. They also describe iterative methods to solve Type 2 ALB problem using known upper and lower bounds on the cycle time. To solve Type 2 ALB problems they iteratively solve Type 1 ALB problems. As they mention, the number of iterations can be as large as the difference between upper bound and lower bound on the cycle time.

Uğurdağ et al. (1997) study a bi-criteria Type 2 ALB problem. Their criteria are minimizing the cycle time and balancing the workload. They assume that the processing times on different workstations are equal and the number of workstations is fixed. To solve Type 2 ALB problem they propose a direct approach in place of a sequence of Type 1 ALB problems. They develop a heuristic procedure to find an initial feasible solution and improve the heuristic solution using a simplex-like algorithm.

Rekiek et al. (1999) study a Type 2 ALB problem that balances the workload between the workstations. They assume that processing times on different workstations are equal. In addition to the precedence relations, they include some preference constraints to separate some tasks and group some others. They develop a genetic algorithm based on grouping idea.

Liu et al. (2005) consider a stochastic Type 2 ALB problem with normally distributed and statistically independent task times. They aim to minimize cycle time given a fixed number of workstations and pre-specified cycle time reliability. They propose a heuristic solution procedure.

Rubinovitz and Bukchin (1993), Bukchin and Tzur (2000), Bukchin and Rubinovitz (2002) and Pekin and Azizoğlu (2008) study ALB problems with equipment decisions.

Rubinovitz and Bukchin (1993) study a Type 1 Robotic Assembly Line Balancing Problem (RALB). They assume that each task requires only single
equipment and only one equipment can be assigned to each workstation. They develop a branch and bound algorithm for small sized problem instances and a heuristic method for large sized problem instances.

Bukchin and Tzur (2000) aim to minimize the total equipment cost by considering the pre-specified cycle time, a single equipment requirement for each task and assignment of a single equipment to each workstation. They develop a Branch and Bound algorithm for moderate sized problem instances. In their algorithm, the workstations are opened sequentially, an equipment is assigned once a workstation is opened and then the tasks are selected. For each partial solution a lower bound is computed, that is found by relaxing some of the model constraints. The node with the smallest lower bound is selected for branching. They develop a Branch and Bound based heuristic for large sized problems by modifying their node selection rule.

Bukchin and Rubinovitz (2002) consider Flexible Assembly Line Design problem with station paralleling. They show that adding parallel stations is equivalent to replacing the equipment with a faster one, hence their model is a special case of Bukchin and Tzur (2000)'s model. They adapt the branch and bound algoritm developed by Buckchin and Tzur (2000) for their problem.

Pekin and Azizoğlu (2008) study a bicriteria Flexible Assembly Line Design problem with pre-specified cycle time. Their criteria are the total equipment cost and the number of workstations. They assume multiple equipments can be assigned to each workstation and a single equipment requirement for each task. They develop a branch and bound algorithm to generate all efficient solutions with respect to two criteria.

The most closely related study to ours is Bukchin and Tzur (2000)'s study. Our study differs from their study in the sense that the number of workstations is fixed and task times and equipment costs are correlated.

## CHAPTER 3

## OUR APPROACH

Recall that our problem P is NP-hard in the strong sense. This justifies the use of an implicit enumeration technique to arrive at an optimal solution. In this study, we propose a branch and bound algorithm to find the optimal assignment of tasks and equipments to the workstations.

The branching schemes designed for classical Assembly Line Balancing (ALB) Problems assign the tasks to the workstations, starting from the first workstation. For the current station, the assignments are considered among the fittable tasks set. A task is called fittable if all its predecessors are assigned either to the current workstation or one of the prior workstations. The current workstation is closed whenever there is no fittable job that can be assigned without exceeding the cycle time.

Our problem differs from the classical branching schemes designed for ALB problems as it includes the equipment decisions.

Through the following theorem we show that the optimal equipment assignment for a given set of assigned tasks is already available.

Theorem 3: Given a set of assigned tasks $S_{c}$ to a workstation, the optimal equipment is the cheapest equipment, $E_{c}$ that satisfies $\sum_{i \in S_{c}} t_{i E_{c}} \leq C T$.

## Proof:

Note from Theorem 1 that there is a single equipment in each workstation. This equipment should be the cheapest one that resides all tasks without exceeding the cycle time en route to minimizing our total equipment cost objective.

As the optimal equipment is available for a given set of tasks, we design our branch and bound algorithm based on task assignments but not on equipment assignments. We decide to close a workstation or not to close it even when there are fittable tasks, since the total task time of the tasks assigned to the current workstation changes according to the equipment assigned. When closing the current workstation we determine the optimal equipment considering the set of tasks assigned to this workstation.

In generating the nodes we make use of the following property.

Property 1: If there is a task that fits to the current workstation with the cheapest equipment $E_{c}$, then branching to a node that represents closing the current workstation cannot lead to a better solution.

## Proof:

Assume a new workstation $k+1$ is opened when there is a task $i$ that fits to the current workstation $k$ with equipment $E_{c}$. Assume $i$ is assigned to one of the succeeding workstations $k+a$., $i$ can be removed from workstation $k+a$ and placed to workstation $k$ without violating the cycle time constraint (as it fits even with the cheapest equipment) and without increasing the total equipment cost ( as the other assignments are kept same). Hence a solution in which $i$ is placed at the current workstation, cannot be worse.

We use the result of the above property in designing our branching scheme. We index the tasks based on the precedence structure. In doing so, we give lower numbers to the tasks that appears as predecessors, i.e., if task $i$ is predecessor of task $j$, then $i<j$. Besides, among the tasks that appear as predecessors the ones with larger number of successors receive higher priority, i.e., we assign lower numbers to these tasks. In order to prevent the duplication of the solutions we always branch to a task with higher index once we are adding to the current workstation. We always add to the current workstation if there is a fittable task
with the cheapest equipment. If there is no fittable task with the cheapest equipment, then we consider the following two branches.

## Branch 1. Close the current workstation (Close Branch)

Assign the cheapest possible equipment (see Theorem 2). Let the equipment assigned be $R$.

## Branch 2. Not to close the current workstation (Not Close Branch)

Consider the equipments $1, \ldots, R+m$ where equipment 1 is the most expensive equipment and $R+m$ is the cheapest equipment that has a fittable task. Thus, when a not close branch is considered for the current workstation the optimal equipment should always be more expensive than the optimal equipment of the corresponding close branch.

In our branch and bound algorithm we first evaluate "Close" branch emanating from a node and continue branching. "Not Close" branch is evaluated during backtracking. We give priority to a "Close" branch as it requires cheaper equipment than "Not Close" branch, hence finding a good upper bound earlier is more likely.

The following figure illustrates our branching scheme.

Figure 2.4 The branch and bound tree

For both "Close" and "Not Close" branches, we first check the feasibility of the partial solution in terms of the number of the workstations. In doing so, we use lower bounds on the number of workstations.

## - "Close" Branches :

We define a lower bound on the number of the workstations, $K_{\min }=\left\lceil\frac{\sum_{i \in U} t_{i 1}}{C T}\right\rceil$
where U is the set of unassigned tasks and $t_{i 1}$ is the time required to perform task $i$ with the most expensive, hence the fastest, equipment.

If $K_{\text {min }}+K_{l}>K$, then the current partial solution that represents closing workstation $K_{l}$ cannot lead to a feasible solution.

If the current solution closes $(K-1)$ st workstation, then the optimal equipment for the next, hence the last, workstation is the largest $m$ that satisfies
$\left\lceil\frac{\sum_{i \in U} t_{i m}}{C T}\right\rceil=1$. In such a case, we update the upper bound, i.e., the best known solution if $\sum_{k=1}^{K-1} E C_{E_{k}}+E C_{r}<U B$, where $E_{k}$ is the equipment assigned to workstation $k$ and $r$ is the optimal equipment for the last workstation.

- "Not Close" Branches :

For a "Not Close" branch of workstation $K_{2}$ a lower bound on the number of the workstations is,
$K_{\text {min }}=\left\lfloor\frac{\sum_{i \in U} t_{i l}}{C T}\right\rfloor$.
If $K_{\text {min }}+K_{2}>K$, then the current partial solution cannot lead to a feasible solution.

We use Property 2 whenever closing a workstation.

Property 2: If task $i$ is assigned to the current workstation, but can be replaced by task $j$ feasibly and $t_{i m} \leq t{ }_{j m}$ for all $m$, then the current assignment cannot lead to a unique optimal solution.

## Proof:

Assume $i$ is assigned to a later workstation $k+a$. Replacing the workstations of $i$ and $j$ is feasible as $j$ can be assigned to the current workstation when $i$ is removed and $i$ can fit any workstation vacated by $j$ as $t_{i m} \leq t_{j m}$ for all $m$. Moreover, such a replacement never increases the number of workstations and
the total equipment cost. This follows that the solution in which $j$ is in the current workstation cannot be worse.

While implementing Property 2, we ask: $t_{i m}<t_{j m}$ at least for one $m$. This is because if $t_{i m}=t_{j m}$ for all $m$, and we fathom a partial solution that represents closing the workstation that includes $i$, then a partial solution that represents closing the workstation that includes $j$ will also be closed.

When closing a workstation, we eliminate some equipment(s) using the results of Properties 3 through 4 stated below.

Property 3: If $\left[\left\lceil\frac{\sum_{i \in U} t_{i 1}}{C T}\right]-1\right] \times E C_{\min }+E C_{m} \geq U B$, where $E C_{\text {min }}$ is the cheapest equipment in the set of remaining equipments, then any further assignment that resides equipment $m$ cannot lead to a unique optimal solution.

## Proof:

Note that $\left[\frac{\sum_{i \in U} t_{i 1}}{C T}\right]$ is a lower bound on the number of workstations. Assume the other workstations are opened with the cheapest equipments and only one workstation is opened with equipment $m$. Such an assignment would have the smallest cost if equipment $m$ has to be used at least once. The associated cost is $\left\lceil\left[\frac{\sum_{i \in U} t_{i 1}}{C T}\right\rceil-1\right] \times E C_{\min }+E C_{m}$. If this cost is no smaller than the smallest known cost, a solution that uses equipment $m$ cannot be unique optimal.

Property 3 is also used for "Not Close" branches by using $\left\lfloor\frac{\sum_{i \in U} t_{i 1}}{C T}\right\rfloor$ as a lower bound on the number of workstations.

We use the below property in eliminating partial solutions and updating the best known solution, $U B$.

Property 4: If $\left\lceil\frac{\sum_{i \in U} t_{i l}}{C T}\right\rceil=1$ then any further assignment that resides equipments $1, \ldots ., l-1$ cannot be optimal.

## Proof:

The minimum cost of completing the partial solution with a single workstation is $E C_{l}$. As $E C_{l}<E C_{l-m}$, a solution that resides equipments $1, \ldots, l-1$ cannot be optimal.

If the condition stated by the above property holds then equipments $1, \ldots, l-1$ are eliminated. Moreover, $U B$ is updated if it is greater than $T C(A)+E C_{l}$ where $T C(A)$ is the equipment cost for already closed workstations.

Note that if $l=L$, i.e., the cheapest equipment justifies a single workstation, then the node is fathomed. This can be generalized if there is a feasible solution with $\left[\frac{\sum_{i \notin A} t_{i 1}}{C T}\right\rceil$ workstations, i.e., minimum number of workstations and cheapest equipment, then it is optimal.

The properties stated above are useful for eliminating relatively expensive equipments. Now we state the properties that enable the elimination of cheaper equipments.

Property 5: If $E C_{m}>E C_{l}$ for two equipments $m$ and $l$, and $t_{i m}=t_{i l}$ for all $i \in U$, then any future assignment with equipment $m$ cannot be optimal.

## Proof:

A solution that resides equipment $m$ cannot be optimal as its cost can be reduced by $E C_{m}-E C_{l}$ units simply by exchanging equipment $m$ with equipment $l$. Note that such an exchange does not affect feasibility as $t_{i m}=t_{i l}$ for all unassigned tasks.

Property 6: Assume $K_{\text {left }}$ and $N_{\text {left }}$ are number of workstations that are not yet used and number of unassigned tasks, respectively.

If $\left(K_{\text {left }}-1\right) \cdot\left\lfloor\frac{C T}{\operatorname{Min}_{i \notin A}\left\{t_{i 1}\right\}}\right\rfloor+\left\lfloor\frac{C T}{\operatorname{Min}_{i \notin A}\left\{t_{i l}\right\}}\right\rfloor<N_{\text {left }}$, then any further assignment that resides equipments $l, \ldots \ldots, L$ cannot be optimal.

## Proof:

$\left\lfloor\frac{C T}{\operatorname{Min}_{i}\left\{t_{i 1}\right\}}\right\rfloor$ is the maximum number of tasks that the most expensive, hence the fastest equipment, can perform in a workstation when the precedence relations are relaxed. Hence, it is an upper bound on the number of tasks that can be performed in a workstation. Similarly, $\left\lfloor\frac{C T}{\operatorname{Min}_{i}\left\{t_{i l}\right\}}\right\rfloor$ is the maximum number of tasks that equipment $l$ can perform in a workstation when the precedence relations are relaxed. Assume the other workstations are opened with the most expensive, hence fastest, equipment and only one workstation is opened with
equipment $l$. Then, $\left(K_{\text {left }}-1\right) \cdot\left\lfloor\frac{C T}{\operatorname{Min}_{i}\left\{t_{i 1}\right\}}\right\rfloor+\left\lfloor\frac{C T}{\operatorname{Min}_{i}\left\{t_{i l}\right\}}\right\rfloor$ is an upper bound on the number of tasks that can be performed in $K_{\text {left }}$ workstations. If the upper bound on the number of tasks that can be performed is less than the number of unassigned tasks then a solution that resides equipment $l$ cannot be feasible. If equipment $l$ satisfies the condition stated in the property then equipments that are cheaper than $l$ satisfy the condition since $t_{i l} \leq t_{i(l+m)}$ for all tasks $i$. This follows that any assignment with equipments $l, \ldots, L$ cannot be optimal.

If the condition stated by the above property holds then equipments $l, \ldots, L$ are eliminated. The elimination of cheaper equipments is important since our first and second lower bounds use the cost of the cheapest equipment that is not eliminated. Eliminating cheaper equipments increases the cost of the cheapest remaining equipment, therefore improves our lower bounds' performances.

Whenever closing a workstation, we update $K$, i.e., the number of workstations to be used. Our initial experiments reveal that an increase in number of workstations significantly increases the solution times of our branch and bound algorithm and all workstations are not necessarily used in the optimal solution. So any reduction in the number of workstations would improve the performance of our branch and bound algorithm.

We now describe the way that we update $K$.

Note that, $n_{L B}=\left\lfloor\frac{C T}{\operatorname{Max}_{l}\left\{\operatorname{Max}_{i}\left\{t_{i l}\right\}\right\}}\right\rfloor$ is a lower bound on the number of tasks that can be performed in a workstation since $\operatorname{Max}_{l}\left\{\operatorname{Max}_{i}\left\{t_{i l}\right\}\right\}$ is the maximum of all task times. This follows that $\left\lfloor\frac{N}{n_{L B}}\right\rfloor$ is an upper bound on the number of workstations required for a feasible solution.

Another valid upper bound on the number of workstations is $\left\lfloor\frac{U B}{E C_{L}}\right\rfloor$. We update $K$ as follows:

$$
K=\operatorname{Min}\left\{K,\left\lfloor\frac{N}{n_{L B}}\right\rfloor,\left\lfloor\frac{U B}{E C_{L}}\right\rfloor\right\}
$$

We calculate lower bounds for each node that cannot be fathomed by our properties. While computing the lower bounds we use the unassigned tasks, remaining equipments and updated $K$ value.

## Lower Bound 1

We consider the special case with identical task times (discussed in Section 2.3) to find a lower bound for our problem P . We let $z$ be an optimal solution to the LP relaxed version of PI. If we set task time $t_{l}$ on equipment $l$ to $\operatorname{Min}_{i}\left\{t_{i l}\right\}$, z gives a lower bound to our problem. We solve the LP relaxed version of PI with $t_{l}$ and let the associated objective function value, z , be $L B_{1}$.

We use $L B_{1}$ for "Close" branches only. Note that each "Close" branch represents a partial solution with set of assigned tasks $A$. In this case, the identical tasks problem for tasks $i \notin A$ is solved to find $L B_{1}$.

When variability of the task times is low, the optimal solution of P is likely to be close to the optimal solution of PI, hence the associated lower bound becomes closer to the optimal objective function value. We illustrate this by two examples given below. The first one exemplifies a case that is unfavorable for $L B_{1}$ whereas the second example illustrates a case where $L B_{1}$ works well.

Example 1: Our example problem has 11 tasks and 5 equipment types. The line has 3 workstations and the required cycle time of the line is 30 time units. The task times and equipment costs are given in Table 3.1.

Table 3.1 Task Times and Equipment Costs of the Example Problem 1

| Tasks Equipments | 1 | 2 | 3 | 4 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 7 | 10 | 10 | 13 | 13 |
| 2 | 6 | 6 | 8 | 12 | 12 |
| 3 | 6 | 6 | 7 | 8 | 10 |
| 4 | 8 | 9 | 10 | 11 | 12 |
| 5 | 6 | 8 | 8 | 9 | 13 |
| 6 | 6 | 8 | 10 | 12 | 12 |
| 7 | 6 | 7 | 7 | 7 | 10 |
| 8 | 8 | 9 | 9 | 10 | 13 |
| 9 | 8 | 11 | 12 | 12 | 13 |
| 10 | 8 | 9 | 9 | 11 | 13 |
| 11 | 6 | 6 | 7 | 9 | 12 |
| Equipment Costs | 400 | 350 | 300 | 250 | 200 |

$t_{l}=\operatorname{Min}_{i}\left\{t_{i l}\right\}=\{6,6,7,7,10\}$
$n_{l}=\left\lfloor\frac{C T}{t_{l}}\right\rfloor=\left\{\left\lfloor\frac{30}{6}\right\rfloor,\left\lfloor\frac{30}{6}\right\rfloor,\left\lfloor\frac{30}{7}\right\rfloor,\left\lfloor\frac{30}{7}\right\rfloor,\left\lfloor\frac{30}{10}\right\rfloor\right\}=\{5,5,4,4,3\}$

Equipments 1 and 3 are eliminated by P6. Equipments 2, 4, 5 are left.
$B=\left\{l \left\lvert\, \frac{N}{n_{l}} \leq K\right.\right\}=\{2,4\}$
$\operatorname{Min}_{l \in B}\left\{\frac{E C_{l}}{n_{l}}\right\}=\operatorname{Min}\left\{\frac{E C_{2}}{n_{2}}, \frac{E C_{4}}{n_{4}}\right\}=\operatorname{Min}\left\{\frac{350}{5}, \frac{250}{4}\right\}=62.5$

So, $b=4$. According to P 5 , there is no need to consider $i=2$, since $\frac{E C_{2}}{n_{2}}>\frac{E C_{4}}{n 4}$.
$L B_{1}=\operatorname{Min}_{i \in\{5\}}\left\{\left(E C_{b} \frac{N-n_{i} \cdot K}{n_{b}-n_{i}}+E C_{i} \frac{n_{b} \cdot K-N}{n_{b}-n_{i}}\right), E C_{b} \frac{N}{n_{b}}\right\}$

$$
\begin{aligned}
& L B_{1}=\operatorname{Min}\left\{\left(E C_{4} \frac{N-n_{5} \cdot K}{n_{4}-n_{5}}+E C_{5} \frac{n_{4} \cdot K-N}{n_{4}-n_{5}}\right), E C_{4} \frac{N}{n_{4}}\right\} \\
& L B_{1}=\operatorname{Min}\left\{\left(250 \frac{11-3 \cdot 3}{4-3}+200 \frac{4 \cdot 3-11}{4-3}\right), 250 \frac{11}{4}\right\}=\operatorname{Min}\{700,687.5\}=687.5
\end{aligned}
$$

Example 2: Our second example problem also has 11 tasks and 5 equipment types. The line has 2 workstations and the required cycle time is 40 time units. Task times and equipment costs are given in the table below.

Table 3.2 Task Times and Equipment Costs of the Example Problem 2

| Tasks Equipments |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | 4 | 5 |
| 1 | 7 | 10 | 10 | 13 | 13 |
| 2 | 6 | 7 | 8 | 12 | 12 |
| 3 | 6 | 7 | 8 | 11 | 12 |
| 4 | 8 | 9 | 10 | 11 | 12 |
| 5 | 6 | 8 | 8 | 11 | 13 |
| 6 | 6 | 8 | 10 | 12 | 12 |
| 7 | 6 | 7 | 8 | 11 | 12 |
| 8 | 8 | 9 | 9 | 11 | 13 |
| 9 | 8 | 11 | 12 | 12 | 13 |
| 10 | 8 | 9 | 9 | 11 | 13 |
| 11 | 6 | 7 | 8 | 11 | 12 |
| Equipment Costs | 400 | 350 | 300 | 250 | 200 |

$t_{l}=\operatorname{Min}_{i}\left\{t_{i l}\right\}=\{6,7,8,11,12\}$
$n_{l}=\left\lfloor\frac{C T}{t_{l}}\right\rfloor=\left\{\left\lfloor\frac{40}{6}\right\rfloor,\left\lfloor\frac{40}{7}\right\rfloor,\left\lfloor\frac{40}{8}\right\rfloor,\left\lfloor\frac{40}{11}\right\rfloor,\left\lfloor\frac{40}{12}\right\rfloor\right\}=\{6,5,5,3,3\}$

Equipments 2 and 4 are eliminated by P6. Equipments 1, 3, 5 are left.
$B=\left\{l \left\lvert\, \frac{N}{n_{l}} \leq K\right.\right\}=\{1\}$. So, $b=1$.
$L B_{1}=\operatorname{Min}_{i \in\{3,5\}}\left\{\left(E C_{b} \frac{N-n_{i} \cdot K}{n_{b}-n_{i}}+E C_{i} \frac{n_{b} \cdot K-N}{n_{b}-n_{i}}\right), E C_{b} \frac{N}{n_{b}}\right\}$
$L B_{1}=\operatorname{Min}\left\{\left(E C_{1} \frac{N-n_{3} \cdot K}{n_{1}-n_{3}}+E C_{1} \frac{n_{1} \cdot K-N}{n_{1}-n_{5}}\right),\left(E C_{1} \frac{N-n_{5} \cdot K}{n_{1}-n_{5}}+E C_{1} \frac{n_{1} \cdot K-N}{n_{1}-n_{5}}\right), E C_{1} \frac{N}{n_{1}}\right\}$

$$
\begin{aligned}
& L B_{1}=\operatorname{Min}\left\{\left(400 \frac{11-5 \cdot 2}{6-5}+300 \frac{6 \cdot 2-11}{6-5}\right),\left(400 \frac{11-3 \cdot 2}{6-3}+200 \frac{6 \cdot 2-11}{6-3}\right), 400 \frac{11}{6}\right\} \\
& L B_{1}=\operatorname{Min}\{700,733.33,733.33\}=700 .
\end{aligned}
$$

## Lower Bound 2

Note that $\left[\frac{\sum_{i} t_{i m}}{C T}\right]$ is a valid lower bound on the number of workstations that use equipment $m$ and the cheaper equipments $m+1, \ldots, L$.
We let $L_{m}=\left\lceil\frac{\sum_{i} t_{i m}}{C T}\right\rceil$.
This follows $\left(L_{m}-1\right) \times E C_{L}+E C_{m}$ is a valid lower bound on the total cost when equipment $m$ and the cheaper equipments are used.

We let $L B_{T C, m}=\left(L_{m}-1\right) \times E C_{L}+E C_{m}$.

An overall lower bound, $L B_{2}$ is available by the following expression.
$L B_{2}=\operatorname{Min}_{m \in M^{\prime}}\left\{L B_{T C, m}\right\}$, where $M^{\prime}=\left\{m \mid L_{m} \leq K\right\}$, i.e., alternatives that produce feasible assignments with respect to the number of workstations.

The following example illustrates $L B_{2}$ computations.

## Example 3:

$$
\begin{aligned}
& C T=10 \quad N=10 \quad K=4 \quad E C_{i}=6-i \quad L=5 \\
& \sum_{i} t_{i 1}=15, \quad \sum_{i} t_{i 2}=20, \quad \sum_{i} t_{i 3}=23, \quad \sum_{i} t_{i 4}=45, \quad \sum_{i} t_{i 5}=52 .
\end{aligned}
$$

$L_{1}=\left\lceil\frac{15}{10}\right\rceil=2, \quad L_{1}<4 \quad$ hence there may exist a feasible solution using only equipment 1 .
$L_{2}=\left\lceil\frac{20}{10}\right\rceil=2, \quad L_{2}<4$ hence there may exist a feasible solution using only equipment 2 and/or equipment 1 .
$L_{3}=\left\lceil\frac{23}{10}\right\rceil=3, \quad L_{3}<4$ hence there may exist a feasible solution using only equipment 3 and/or equipments 1 and 2 .
$L_{4}=\left\lceil\frac{45}{10}\right\rceil=5, \quad L_{4}>4$ hence there cannot exist a feasible solution using equipment 4.
$L_{5}=\left\lceil\frac{52}{10}\right\rceil=6, \quad L_{5}>4$ hence there cannot exist a feasible solution using equipment 5 .

This follows, $M^{\prime}=\{1,2,3\}$.

$$
\begin{aligned}
& L B_{T C, 1}=\left(L_{1}-1\right) \times E C_{5}+E C_{1}=1+5=6 \\
& L B_{T C, 2}=\left(L_{2}-1\right) \times E C_{5}+E C_{2}=1+4=5 \\
& L B_{T C, 3}=\left(L_{3}-1\right) \times E C_{5}+E C_{3}=2+3=5 \\
& L B_{2}=\operatorname{Min}_{m \in M^{\prime}}\left\{L B_{T C, m}\right\}=\operatorname{Min}\{6,5,5\}=5
\end{aligned}
$$

$L B_{2}$ is used as a filtering mechanism as it runs quicker when compared to $L B_{1}$ and $L B_{3}$. We first calculate $L B_{2}$, if it cannot eliminate a partial solution, i.e., $T C_{c}+L B_{2}<U B$, then we calculate $L B_{1}$ or $L B_{3}$.

As $L B_{2}$ is an easy-to-find lower bound, we use it for both "Close" and "Not close" branches.

For "Close" branches, the lower bound is found considering the unassigned tasks and remaining equipments (not eliminated by equipment elimination rules).

Formally,
$L_{m}=\left\lceil\frac{\sum_{i \notin A} t_{i m}}{C T}\right\rceil$ where $A$ is the set of assigned tasks.
$L B_{2}(A)=\operatorname{Min}_{m \in M^{\prime \prime}}\left\{L B_{T C, m}\right\}$ where $M^{\prime \prime}=\left\{m \mid L_{m}(A) \leq K\right.$ and $\left.k \in \bar{E}\right\}$
and $\bar{E}$ is the set of remaining equipments

For "Not close" branches, the lower bound is again found considering the unassigned tasks and remaining equipments. Lower bound on the number of workstations to be used when equipment $m$ and cheaper equipments becomes, $L_{m}=\left\lfloor\frac{\sum_{i \notin A} t_{i m}}{C T}\right\rfloor$ where $A$ is the set of assigned tasks.

We calculate $L B_{2}(A)$ as in "Close" branches.
$L B_{2}(A)=\operatorname{Min}_{m \in M "}{ }^{\prime \prime}\left\{L B_{T C, m}\right\}$ where $M^{\prime \prime}=\left\{m \mid L_{m}(A) \leq K\right.$ and $\left.k \in \bar{E}\right\}$ and $\bar{E}$ is the set of remaining equipments.

## Lower Bound 3

Recall that Bukchin and Tzur (2000) aim to minimize the total equipment cost by considering the cycle time and precedence relations. There is no restriction on the number of workstations used. Single equipment for each task is assumed and single equipment assignment to each workstation is allowed.

Bukchin and Tzur (2000) propose a lower bound that is obtained by relaxing some of the constraints and surrogating some of them. The relaxed constraints
are the precedence constraints. The surrogate constraint is due to the cycle time. They sum the cycle time constraints over all workstations for all equipment and obtain an aggregate cycle time constraint over all equipments. After the relaxations, the constraint set that ensures at most one equipment for each workstation becomes redundant. Hence all workstations are considered together. The resulting formulation and new decision variables are given below.
$y_{l}=\sum_{k=1}^{N} y_{l k}=$ total number of type $l$ equipment.
$x_{i l}=\sum_{k=1}^{N} x_{i l k}= \begin{cases}1 & \text { if task } i \text { is assigned to equipment } l, \\ 0 & \text { otherwise } .\end{cases}$
$\operatorname{Min} \sum_{l=1}^{L} E C_{l} y_{l}$
$\sum_{l=1}^{L} x_{i l}=1 \quad \forall i$
$\sum_{i=1}^{N} t_{i l} x_{i l} \leq C T \cdot y_{l} \quad \forall l$
$x_{i l} \in\{0,1\} \quad \forall i, l$
$y_{l} \quad$ integer $\quad \forall l$

Constraint set (13) ensures that each task is assigned to one equipment. Constraint set (14) is the surrogate cycle time constraint. Constraint sets (15) and (16) are the integrality constraints.

After relaxing constraint set (16), the solution for the resulting problem becomes available by the following expression.
$x_{i l}=\left\{\begin{array}{ll}1 & \text { if } E C_{l} \cdot t_{i l}=\min _{j}\left\{E C_{j} \cdot t_{i j}\right\}, \\ 0 & \text { otherwise. }\end{array} \quad \forall i\right.$
$y_{l}=\sum_{i=1}^{N} \frac{t_{i l} \cdot x_{i l}}{C T}$
$\forall j$

Then a lower bound on the original problem is available through the following expression,
$L B_{3}=\sum_{l=1}^{L} E C_{l} y_{l}$

A lower bound on any relaxation of a minimization problem is a valid lower bound on the original problem. Bukchin and Tzur (2000)'s problem assumes no limit on the number of workstations; hence it is a relaxation to our problem. This follows; $L B_{3}$ is a valid lower bound to our problem.

We use $L B_{3}$ for "Close" branches only. Note that each "Close" branch represents a partial solution with set of assigned tasks $A$. In this case, the relaxed problem for tasks $i \notin A$ and remaining equipments is solved in order to find $L B_{3}$.

We illustrate the calculation of $L B_{1}$ and $L B_{3}$ on two simple examples. In the first one $L B_{3}$ works better than $L B_{1}$ whereas in the second one $L B_{1}$ performs better.

Example 4: Suppose there are 11 tasks and 5 equipments. The line has 3 workstations and the required cycle time is 30 time units. Task times and equipment costs are given in table below.

Table 3.3 Task Times and Equipment Costs of the Example Problem 4

| Tasks Equipments |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | 4 | 5 |
| 1 | 7 | 10 | 10 | 13 | 13 |
| 2 | 6 | 6 | 8 | 12 | 12 |
| 3 | 6 | 6 | 7 | 8 | 10 |
| 4 | 8 | 9 | 10 | 11 | 12 |
| 5 | 6 | 8 | 8 | 9 | 13 |
| 6 | 6 | 8 | 10 | 12 | 12 |
| 7 | 6 | 7 | 7 | 7 | 10 |
| 8 | 8 | 9 | 9 | 10 | 13 |
| 9 | 8 | 11 | 12 | 12 | 13 |
| 10 | 8 | 9 | 9 | 11 | 13 |
| 11 | 6 | 6 | 7 | 9 | 12 |
| Equipment Costs | 400 | 350 | 300 | 250 | 200 |

$E C_{j} \cdot t_{i j}$ values are shown in the table below.

Table 3.4 Equipment Costs x Task Times for the Example Problem 4

| Tasks | Equipments |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 2800 | 3500 | 3000 | 3250 | 2600 |
| 2 | 2400 | 2100 | 2400 | 3000 | 2400 |
| 3 | 2400 | 2100 | 2100 | 2000 | 2000 |
| 4 | 3200 | 3150 | 3000 | 2750 | 2400 |
| 5 | 2400 | 2800 | 2400 | 2250 | 2600 |
| 6 | 2400 | 2800 | 3000 | 3000 | 2400 |
| 7 | 2400 | 2450 | 2100 | 1750 | 2000 |
| 8 | 3200 | 3150 | 2700 | 2500 | 2600 |
| 9 | 3200 | 3850 | 3600 | 3000 | 2600 |
| 10 | 3200 | 3150 | 2700 | 2750 | 2600 |
| 11 | 2400 | 2100 | 2100 | 2250 | 2400 |

$x_{i l}=\left\{\begin{array}{ll}1 & \text { if } E C_{l} \cdot t_{i l}=\min _{j}\left\{E C_{j} \cdot t_{i j}\right\}, \\ 0 & \text { otherwise. }\end{array} \quad \forall i\right.$
$y_{l}=\sum_{i=1}^{N} \frac{t_{i l} \cdot x_{i l}}{C T}$
$\forall j$

Using the equations above, we get:
$x_{15}=1, x_{22}=1, x_{35}=1, x_{45}=1, x_{54}=1, x_{61}=1, x_{74}=1, x_{84}=1, x_{95}=1$,
$x_{10,5}=1, x_{11,3}=1$.
$y_{1}=\frac{t_{61} \cdot x_{61}}{C T}=\frac{6}{30}=0.2$
$y_{2}=\frac{t_{22} \cdot x_{22}}{C T}=\frac{6}{30}=0.2$
$y_{3}=\frac{t_{11,3} \cdot x_{11,3}}{C T}=\frac{6}{30}=0.2$
$y_{4}=\frac{t_{54} \cdot x_{54}}{C T}+\frac{t_{74} \cdot x_{74}}{C T}+\frac{t_{84} \cdot x_{84}}{C T}=\frac{9+7+10}{30}=0.86$
$y_{5}=\frac{t_{15} \cdot x_{15}}{C T}+\frac{t_{35} \cdot x_{35}}{C T}+\frac{t_{45} \cdot x_{45}}{C T}+\frac{t_{95} \cdot x_{95}}{C T}+\frac{t_{10,5} \cdot x_{10,5}}{C T}$
$y_{5}=\frac{13+10+12+13+13}{30}=2.033$
$L B_{3}=\left\lceil\sum_{l=1}^{L} E C_{l} y_{l}\right\rceil=400 \cdot 0.2+350 \cdot 0.2+300 \cdot 0.2+250 \cdot 0.86+200 \cdot 2.033$
$L B_{3}=832$

Recall that for the same example problem $L B_{1}$ is found to be 688 . For this problem $L B_{3}$ works better.

Example 5: There are 11 tasks and 5 equipments. The line has 2 workstations and the required cycle time is 40 time units. Task times and equipment costs are given in the table below.

Table 3.5 Task Times and Equipment Costs of the Example Problem 5

| Tasks Equipments |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 7 | 10 | 10 | 13 | 13 |
| 2 | 6 | 7 | 8 | 12 | 12 |
| 3 | 6 | 7 | 8 | 11 | 12 |
| 4 | 8 | 9 | 10 | 11 | 12 |
| 5 | 6 | 8 | 8 | 11 | 13 |
| 6 | 6 | 8 | 10 | 12 | 12 |
| 7 | 6 | 7 | 8 | 11 | 12 |
| 8 | 8 | 9 | 9 | 11 | 13 |
| 9 | 8 | 11 | 12 | 12 | 13 |
| 10 | 8 | 9 | 9 | 11 | 13 |
| 11 | 6 | 7 | 8 | 11 | 12 |
| Equipment Costs | 400 | 350 | 300 | 250 | 200 |

$E C_{j} \cdot t_{i j}$ values are shown in the table below.

Table 3.6 Equipment Costs x Task Times for the Example Problem 5

| Tasks | Equipments |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | 4 | 5 |
| 1 | 2800 | 3500 | 3000 | 3250 | 2600 |
| 2 | 2400 | 2450 | 2400 | 3000 | 2400 |
| 3 | 2400 | 2450 | 2400 | 2750 | 2400 |
| 4 | 3200 | 3150 | 3000 | 2750 | 2400 |
| 5 | 2400 | 2800 | 2400 | 2750 | 2600 |
| 6 | 2400 | 2800 | 3000 | 3000 | 2400 |
| 7 | 2400 | 2450 | 2400 | 2750 | 2400 |
| 8 | 3200 | 3150 | 2700 | 2750 | 2600 |
| 9 | 3200 | 3850 | 3600 | 3000 | 2600 |
| 10 | 3200 | 3150 | 2700 | 2750 | 2600 |
| 11 | 2400 | 2450 | 2400 | 2750 | 2400 |

Now we get:
$x_{15}=1, x_{21}=1, x_{31}=1, x_{45}=1, x_{51}=1, x_{61}=1, x_{75}=1, x_{85}=1, x_{95}=1$,
$x_{10,5}=1, x_{11,3}=1$.
$y_{1}=\frac{t_{21} \cdot x_{21}}{C T}+\frac{t_{31} \cdot x_{31}}{C T}+\frac{t_{51} \cdot x_{51}}{C T}+\frac{t_{61} \cdot x_{61}}{C T}=\frac{6+6+6+6}{40}=0.6$
$y_{2}=0$
$y_{3}=\frac{t_{11,3} \cdot x_{11,3}}{C T}=\frac{8}{40}=0.2$
$y_{4}=0$
$y_{5}=\frac{t_{15} \cdot x_{15}}{C T}+\frac{t_{45} \cdot x_{45}}{C T}+\frac{t_{75} \cdot x_{75}}{C T}+\frac{t_{85} \cdot x_{85}}{C T}+\frac{t_{95} \cdot x_{95}}{C T}+\frac{t_{10,5} \cdot x_{10,5}}{C T}$
$y_{5}=\frac{13+12+12+13+13+13}{40}=1.9$
$L B_{3}=\sum_{l=1}^{L} E C_{l} y_{l}=400 \cdot 0.6+350 \cdot 0+300 \cdot 0.2+250 \cdot 0+200 \cdot 1.9$
$L B_{3}=680$

Recall that for the same example problem $L B_{1}$ is found to be 700 . For this problem $L B_{1}$ works better.

## CHAPTER 4

## COMPUTATIONAL EXPERIMENTS

In this chapter we discuss the results of our experiment that is designed to test the performance of our branch and bound algorithm together with the reduction and bounding mechanisms. We take the precedence networks from open literature for varying sizes of tasks. We use precedence graphs included in the data sets of Scholl (1993) at the website http://www.assembly-linebalancing.de/

We generate the task times as follows: The shortest task times, $t_{i 1}$, are generated randomly from discrete uniform distribution between 1 and 6 . Then the second shortest task times, i.e., the task times of the second expensive equipment, $t_{i 2}$, are generated randomly as $t_{i 2}=r_{i} \times t_{i 1}$, where $r_{i}$ is uniform between 1 and 1.4. Similarly, we generate $t_{i(l+1)}$ as $r_{i} \times t_{i l}$ using $t_{i l}$ and $r_{i}$ values. Note that to find the task times on each equipment, we generate different $r_{i}$ values.

We set the number of equipments, $L$, to 5 . Our initial experiments showed that the number of equipments does not have a significant effect on the performance of our algorithm. Hence we try a single value of 5 for $L$. We generate the following two sets of equipment costs.

$$
\begin{array}{llllll}
\text { Set I } & E C_{1}=400 & E C_{2}=350 & E C_{3}=300 & E C_{4}=250 & E C_{5}=200 \\
\text { Set II } & E C_{1}=400 & E C_{2}=375 & E C_{3}=350 & E C_{4}=325 & E C_{5}=300
\end{array}
$$

Note that Set I resides low equipment cost and Set II resides high equipment cost problem instances. Sets I and II also correspond to high and low cost variability cases, respectively.

We use three different sets for cycle times: namely C1, C2 and C3. C1 resides the instances with small cycle time, $C 2$ has cycle times that is 50 percent more than the cycle time of $C 1$ and $C 3$ has cycle times that is two times the cycle time of $C 1$.

We set the cycle time of $C 1$ as $\left[\frac{\sum_{i} \sum_{l} t_{i l}}{L \times K}\right\rceil$, where $L$ is the number of equipments and $K$ is the number of workstations. $\frac{\sum_{i} \sum_{l} t_{i l}}{L}$ is the expected total processing time and $\left[\frac{\sum_{i} \sum_{l} t_{i l}}{L \times K}\right\rceil$ gives the expected cycle time when all $K$ workstations are used.

Hence for each value of $N$ and $K$ we use six combinations of cycle times and equipment cost values.

We vary the number of tasks, $N$, between 20 and 55 , in increments of 5 , i.e., we use 8 different $N$ values for $C 1$ and $C 2$. For $C 3$, We vary $N$ between 20 and 55, in increments of 5 and between 60 and 80 in increments of 10, i.e., we use 11 different $N$ values We vary the number of workstations, $K$, between 2 and 8 , in increments of 2, i.e., we use 4 different $K$ values.

Hence for $C 1$ and $C 2$, we have $2 \times 8 \times 4=64$ each and for $C 3$, we have $2 \times 11 \times 4=88$ combinations. For each combination we generate 10 problem instances. As a total, we solve 2160 problems.

We code our algorithms in C programming language and implement on Intel Core 2 Duo, $2.33 \mathrm{GHz}, 980 \mathrm{MB}$ of RAM PC.

For each problem instance, we set a termination limit of 2 hours. We terminate the execution of the branch and bound algorithm if it does not return a solution
in 2 hours. We record the number of nodes searched and best solution reached at termination.

The rest of the chapter is organized as follows: In Section 4.1., we state the statistics we used to evaluate the performances of the lower bounds and branch and bound algorithm. In Section 4.2, we present our preliminary experiment for selecting the bounding mechanisms to be used in the main experiment. We also test the effectiveness of the reduction mechanisms, by comparing two branch and bound algorithms: one with reduction mechanisms and one without reduction mechanisms. The preliminary experiment includes small-sized problem instances and the main experiment includes large-sized problem instances. In the main experiment we use the bounding mechanisms that are returned as most efficient by the preliminary experiment.

### 4.1. STATISTICS USED

We use the following statistics to evaluate the performance of our branch and bound algorithm.

- Average computation time in Central Processing Unit (CPU) seconds (Average CPU Time)
- Maximum CPU Time
- Average number of nodes searched
- Maximum number of nodes searched
- Average node number till the optimal solution is found (Average optimality node)
- Maximum optimality node

To evaluate the performance of the lower bounds we use average and maximum deviation of the lower bound from the optimal cost as a ratio of the optimal node. Formally, $L B_{i} D=$ Percent deviation of the lower bound at the root node $=\frac{O P T-L B_{i}}{O P T} \times 100$,
where $O P T$ is the total equipment cost and $L B_{i}$ is the total cost found by lower bound $i$ at the root node.

### 4.2. PRELIMINARY RUNS

Our preliminary runs include the following problem combinations:
$N=20,25$ and 30
$K=2,4,6$ and 8
$C T=C 1$ and $C 2$
$E C=$ Set I and Set II

We have $3 \times 4 \times 2 \times 2=48$ combinations. We generate 10 problem instances for each combination. Hence a total of 480 problems are solved.

The aim of these runs is to select the lower bound(s) to be used for larger sized problem instances. We let $B A B_{i}$ be the branch and bound algorithm that uses only lower bound $i . B A B_{i j}$ is the branch and bound algorithm that uses first lower bound $i$ and then lower bound $j$ if lower bound $i$ cannot fathom. We try $B A B_{1}, B A B_{2}, B A B_{3}, B A B_{21}$ and $B A B_{23}$. We exclude $B A B_{13}$ from even preliminary runs, as our limited runs had revealed that the reductions obtained in node eliminations could not lead to a reduction in CPU times. As $L B_{2}$ is an easy-to-compute bound, it is used as a filtering mechanism before $L B_{1}$ and $L B_{3}$.

We report the average number of nodes and CPU times for equipment cost sets Set I and Set II, in Table 4.1 and Table 4.2, respectively. The associated worst case, i.e., maximum, results are given in Appendix in Tables A. 1 and A.2. The tables also include the results for a branch and bound algorithm that uses no lower bounds, namely $B A B_{0}$.

Table 4.1 The branch and bound performances with different lower bounds, Set I

| CT | N | K | $\mathrm{BAB}_{1}$ |  | $\mathrm{BAB}_{2}$ |  | $\mathrm{BAB}_{3}$ |  | $\mathrm{BAB}_{21}$ |  | $\mathrm{BAB}_{23}$ |  | $\mathrm{BAB}_{0}$ |  |

As can be observed from the tables, $B A B_{2}$ and $B A B_{3}$ perform better than $B A B_{1}$. The poor performance of $B A B_{1}$ can be attributed to the high variability of the task times where the minimum task time may be too far from many task times. In comparing the performances of $B A B_{0}$ and $B A B_{1}$, we observe that $L B_{1}$ cannot lead to a significant reduction in the average number of nodes searched. When $L B_{2}$ is used before $L B_{I}$ only a slight reduction in the average number of nodes is observed over $B A B_{2}$ and the corresponding average CPU times are a slightly higher. Hence, the savings in the number of nodes is outweighed by the increased CPU times.

The effort spent in calculating the lower bounds is significantly justified in $B A B_{2}$ and $B A B_{3}$. We can see that there is a considerable reduction in the average number of nodes and CPU times over $B A B_{0}$. These reductions are more significant when the number of tasks and workstations are larger. For example, for Set I, $C 2, N=30$ and $K=8$, when $B A B_{2}$ is used the average number of nodes and CPU time are reduced from $34,816,002$ to $16,899,066$ and from 41.595 seconds to 26.411 seconds, respectively. Moreover, when $B A B_{3}$ is used the average number of nodes is reduced to $12,034,730$ and the resulting average CPU time is 18.603 seconds. However this result cannot be generalized and the branch and bound algorithms do not dominate each other. For example, when Set I, $C 2, N=30$ and $K=6$, the average number of nodes is 929,092 for $B A B_{2}$ and $1,711,128$ for $B A B_{3}$. The corresponding average CPU times are 1.408 and 2.344 seconds.

The average number of nodes and CPU times are higher when the equipment costs are more variable and the cycle time is smaller. Note that Set I and C1 form the hardest combination. Furthermore, as the number of workstations and number of tasks increase the average CPU times tend to increase exponentially.

Moreover, to see whether it is worth to use our elimination rules or not, we perform an experiment using $B A B_{2}$ and $B A B_{23}$. We design two branch and bound algorithms: one using these mechanisms and one not using them. We
report the average performances in Table 4.3. The associated worst case performances are reported in Appendix, Table A.3.

It can be observed from the tables that our reduction mechanisms improve the performance of both $B A B_{2}$ and $B A B_{23}$ considerably. As the number of tasks and workstations increase the reductions in the average number of nodes and CPU times are more significant. For example, when Set I, $C 2, N=30$ and $K=8$, the use of reduction mechanisms in $B A B_{2}$ and $B A B_{23}$ reduce average CPU times from 108.027 seconds to 26.411 seconds and from 45.702 to 14.967 , respectively.

As a result of our preliminary experiments we see that the branch and bound algorithm, that uses our reduction mechanisms and $L B_{2}$ before $L B_{3}$ as a filtering mechanism, i.e., $B A B_{23}$, performs superior.

Table 4.3 The effect of the reduction mechanisms

### 4.3. MAIN EXPERIMENT

In this section we report on the performance of our branch and bound algorithm that is selected for larger sized problem instances in the previous section, i.e., $B A B_{23}$. We present the results of our main runs in Tables 4.4 through 4.9. Specifically, we report the results of Set I and C1 in Table 4.4, Set II and C1 in Table 4.5, Set I and C2 in Table 4.6, Set II and C2 in Table 4.7, Set I and C3 in Table 4.8, Set II and C3 in Table 4.9.

As can be observed from the tables, as the number of workstations, $K$, increases, both the average and maximum number of nodes and the CPU times increase significantly. The same result is true for the number of nodes till optimality. An increase in the average and maximum CPU times are more significant when $N \geq 30$. For example, for 45 tasks problem, when equipment costs with high variability, i.e., Set I and low cycle time, C1 are used, we can see from Table 4.4 that for $K=2$, the maximum CPU time is less than 2 seconds whereas for $K=4,9$ out of 10 instances cannot be solved in 2 hours.

When all other parameter combinations are fixed, the equipment cost set with higher variability, i.e., Set I is more difficult than the equipment cost set with lower variability, i.e., Set II. It can be observed from Tables 4.4 and 4.5 that almost all performance measures are better for Set II. For example in Table 4.4 (Set I ) for $N=30, K=8$, the average CPU time is about 165 seconds whereas in Table 4.5 (Set II) the average CPU time is about 74 seconds. Some larger sized problems that could not be solved in 2 hours with equipment cost Set I, can be solved with Set II. The similar observations hold for the results in Tables 4.6 and 4.7 (C1) as well as Tables 4.8 and 4.9 (C2).

Another important conclusion from the tables is that the cycle time has significant influence on the difficulty of the problem. As the cycle time increases, the number of nodes searched, CPU times, number of nodes till optimality decrease considerably. This influence is expected since higher cycle times enable optimal solutions with fewer workstations and the reduction rules for the number of workstations become more effective. When the cycle time is higher we have fewer workstations as more tasks can fit to a workstation. The reduction in CPU times becomes more significant when the number of tasks and workstations are higher. Note from Tables 4.4, 4.6 and 4.8 that when $N=50, K=8$ and Set I , for $C 1, C 2$ and $C 3$ the average CPU times are about 957, 22 and 4 seconds, respectively. Theoretically, the generated cycle time values may not return a feasible solution, however in our experiments we always had feasible solutions.

Our experiments reveal that the most difficult combination of equipment costs and cycle time is Set I and Cl (see Table 4.4) whereas the easiest combination is Set II and C3 (see Table 4.9). In the most difficult combination set, none of the instances with $N=40$ and $K=6$ and 8 can be solved in 2 hours. On the other hand, in the easiest combination set, all of the instances are solved with average CPU times less than 4 seconds for $K=6$ and 218 seconds for $K=8$. Moreover, for $N=45$ and $K=4,9$ out of 10 instances cannot be solved in 2 hours in the most difficult combination. However, in the easiest combination set, the average CPU time for instances with $N=45$ and $K=8$ is less than 779 seconds.

In general, the average and maximum number of nodes till optimality is very low compared to number of nodes searched especially for larger $K$ and $N$. For example for $N=40, K=6, T C=$ Set II and $C T=\mathrm{C} 2$ (Table 4.7), the average number of nodes till optimality is $4,918,229$ although the average number of nodes searched is $196,985,643$. Hence, the problems that cannot be solved until our termination limit of 2 hours are likely to be optimal.

The average performances of the majority of the instances are close to their maximums. This reveals the consistent behavior of our branch and bound algorithm over all instances. However there is an exception in Table 4.9 for $N=55$ and $K=6$ where the average CPU time is about 182 seconds whereas the maximum CPU time is about 1282 seconds. We see that 2 of 10 instances have CPU times of 516 and 1282 seconds and the remaining eight instances are solved in about 2.7 seconds.

Generally, as the number of tasks increases, the average and maximum number of nodes searched, CPU times and number of nodes till optimality increase. This is expected since the number of tasks affects the number of branches, hence the depth of the tree. However, we observe some exceptions in our tables between $N=30$ and $N=35$, and between $N=45$ and $N=50$. This may be due to random effect or the precedence structure. When precedence relations are fewer, more branches become feasible, hence the problem gets harder.

The flexibility of the precedence graphs is measured by flexibility ratio, FR.
$F R=\frac{\text { Number of zerosin the precedence network }}{\frac{N \times(N-1)}{2}}$, where an entry $(i, j)$ of the precedence network is 1 if task $i$ precedes task $j$ and 0 otherwise. Note that $\frac{N \times(N-1)}{2}$ gives the total number of entries in the precedence network. As FR increases problem becomes less restricted, hence more difficult to solve.

We calculate FR ratios for our test problems and tabulate the results in Table 4.10.

Table 4.10 The Flexibility Ratios of test problems

| $\mathbf{N}$ | FR |
| :---: | ---: |
| 20 | 0.2300 |
| 25 | 0.2833 |
| 30 | 0.5517 |
| 35 | 0.4050 |
| 40 | 0.6435 |
| 45 | 0.5545 |
| 50 | 0.1812 |
| 55 | 0.4471 |
| 60 | 0.3379 |
| 70 | 0.4058 |
| 80 | 0.4399 |

We find that for $N=30$ and $N=35, F R$ is 0.5517 and 0.4050 , respectively. Thus, when $N=35$ the instances are more flexible which can explain the exception. Moreover, note that for $N=45$ and $N=50, F R$ values are 0.5545 and 0.1812 , respectively. Hence, we can explain the lower CPU times returned by the larger size problems by their lower flexibility ratios.

In practice, the flexibility ratios of the assembly lines are generally lower. Note from Table 4.10 that all the precedence networks we use have relatively high ratios. Bukchin and Tzur (2000) use $F R$ values that are around 0.1 and 0.4 . Hence our experiments consider relatively difficult to solve ones.

We next investigate root node lower bound performances. Tables 4.11, 4.12 and 4.13 report the average and maximum deviations of $L B_{1}, L B_{2}$ and $L B_{3}$ from the optimal for $C 1, C 2$ and $C 3$, respectively.

Table 4.13 The lower bound performances, C3

Recall that $B A B_{2}$ and $B A B_{3}$ perform better than $B A B_{1}$. It can be observed from Tables 4.11, 4.12 and 4.13 that the average and maximum deviations of $L B_{2}$ and $L B_{3}$ are very low compared to deviations of $L B_{1}$. This verifies that the performance of the branch and bound algorithms is very much influenced from the quality of the lower bounds.

We observe from the tables that $L B_{2}$ and $L B_{3}$ do not consistently outperform each other. The average and maximum deviations of $L B_{2}$ decrease as the equipment cost variability, i.e., difference between equipment costs, decreases. This is due to the fact that the cheapest equipment cost is used in calculating $L B_{2}$. Note that, $L B_{2}$ finds the optimal solution at root node for $K=2$ when the cycle time is larger ( $C 2$ and $C 3$ ).

Recall that $L B_{3}$ is designed when there is no limit on the number of workstations. So, we expect that $L B_{3}$ works better in instances with higher number of workstations. It can be observed from the tables that the average and maximum deviations of $L B_{3}$ decrease as the number of workstations increases.

To set the limit of our branch and bound algorithm in terms of the number of tasks and number of workstations we design a small experiment with 60,70 and 80 tasks problem instances for C3. The results are tabulated in Table 4.16. Note that $C 3$ is relatively easier than $C 1$ and $C 2$. The results of our main experiment indicate that these problem sizes could not be solved in two hours with $C 1$ and $C 2$.

As can be observed from the table for $N=60$ all the instances are solved in two hours. When $N=70$, for Set I up to 6 workstations are solved whereas for Set II up to 8 workstations are solved. For $N=80$, when Set I is used, the instances up to 4 workstations are solved whereas when Set II is used and $K$ is set to 6,3 out of 10 instances remain unsolved after two hours.

## CHAPTER 5

## CONCLUSIONS

In this study, we develop an exact algorithm for a Flexible Assembly Line Design problem with fixed number of workstations. We assume the task times and equipment costs are correlated in the sense that the cheaper equipment gives no smaller task times. Given the cycle time we find the assignment of tasks and equipments to the workstations with minimum total equipment cost. In doing so, we develop a branch and bound algorithm that uses powerful lower bounds and reduction mechanisms. We also study a special case of the problem with identical task times and discuss the way we benefit from this case in developing a lower bound.

We design an experiment to test the performance of our branch and bound algorithm together with the reduction and bounding mechanisms. The number of tasks and number of workstations are the main factors that affect the difficulty of the problem. Generally, as the number of tasks and number of workstations increase, the solution times increase. We also observe that as the cycle time increases, the complexity of the solutions decreases. The results of our computational experiments reveal that in our termination limit of two hours up to 80 tasks with 6 workstations and 70 tasks with 8 workstations are solved when cycle time is large. When medium cycle time is used, up to 55 tasks and 6 workstations are solved, when cycle time is small up to 50 tasks and 8 workstations can be solved.

Other important factors that affect problem difficulty are the equipment costs and the flexibility ratio of the precedence relations. As the variability between the equipment costs decreases, the solution times decrease considerably. We observe the most difficult combination when the cycle time is low and the variability between equipment costs is high. Moreover we find that as an increase in the flexibility ratio adds to the difficulty of the solutions.

In general, the average and maximum number of nodes till optimality is very low compared to the number of nodes searched, in particular when $K$ and $N$ are large. Hence, one can use our branch and bound algorithm as a truncated approach if the guarantee of optimality is not as essential. In most of the instances the average performances are close to the maximums indicating the consistent behavior of our branch and bound algorithm. Moreover, our lower bounding procedures and reduction mechanisms are found to be very effective in reducing the size of the search.

To the best of our knowledge our study is the first attempt to solve the Flexible Line Design problem with fixed number of workstations. We hope our study helps to open new research areas most noteworthy of which are discussed below:

- In this study, we considered correlated task times and equipment costs. General task times and equipment costs may be a worth-studying extension.
- We used deterministic task times. Using stochastic task times may be considered as a future study.
- We assume all tasks are performed by a single equipment. Multiple equipments (tools) per task case can be a challenging research area.
- We take the cycle time as a constraint. The cycle time may be treated as a decision variable.
- Heuristic procedures -using our reduction and bounding mechanisms-may be developed to solve larger sized problem instances.
- We assume all equipments can perform all tasks, a reasonable extension may be to assume each equipment is eligible to perform only a subset of tasks.
