ABSTRACT

SYNTHESIS AND CHARACTERIZATION OF NOVEL RARE EARTH PHOSPHATES AND RIETVELD STRUCTURAL ANALYSIS OF RARE EARTH ORTHOBORATES

Seyyidođlu, Semih

Ph.D., Department of Chemistry

Supervisor: Assoc.Prof.Dr. Ayşen Yılmaz

Co-Supervisor: Prof.Dr. Macit Özenbaş

September 2009, 209 pages

This thesis covers the synthesis and the characterization of sodium lanthanide oxide phosphates, rare earth added strontium pyrophosphates and the Rietveld structural analysis of rare earth orthoborates. Solid state and microwave-assisted synthesis method was employed for the synthesis of desired materials. The formation of the produced phases was confirmed by X-ray Diffraction (XRD), Infrared FT-IR, Raman, Scanning Electron Microscopy (SEM) methods. By using Rietveld Refinement method, structural analysis of rare earth orthoborates were done and three dimensional crystal structures were found.

In the first part of the thesis, some new sodium lanthanide oxide phosphates were synthesized by solid state reaction method from Ln_2O_3 (where $\text{Ln} = \text{La, Nd, Sm, Gd, Dy, Ho, Er, Yb}$), Na_2CO_3 , $\text{NH}_4\text{H}_2\text{PO}_4$ at 1100 °C. $\text{Na}_2\text{LaOPO}_4$, $\text{Na}_2\text{NdOPO}_4$, and $\text{Na}_2\text{SmOPO}_4$ produced with the space group is $Pmm2$. With the help of the same procedure new orthorhombic $\text{Na}_2\text{DyOPO}_4$, $\text{Na}_2\text{HoOPO}_4$, $\text{Na}_2\text{ErOPO}_4$, and $\text{Na}_2\text{YbOPO}_4$ were synthesized for the first time in the literature at 1100 °C with the same space group $Pmm2$.

In the second part of the thesis, $\text{Sr}_2\text{P}_2\text{O}_7$ - ZrP_2O_7 solid solution was obtained by the solid state reaction and they were characterized for the first time in literature and subjected to thermoluminescence measurements showing $\text{Sr}_2\text{P}_2\text{O}_7$ has glow curve around 100 °C. Then CuO and some rare earth oxides (Y_2O_3 , La_2O_3 , CeO_2 , Pr_6O_{11} , Nd_2O_3 , Sm_2O_3 , Eu_2O_3 , Gd_2O_3 , Tb_2O_3 , Dy_2O_3 , Ho_2O_3 , Er_2O_3 , Tm_2O_3 , Yb_2O_3 , Lu_2O_3) 0.5-15% (by weight) were added to pure $\text{Sr}_2\text{P}_2\text{O}_7$. After structural determinations by XRD, thermoluminescence studies showed two glow peaks of Pr, Ho, and Nd along with Cu-added samples, one of them is always at around 90 °C and the other TL-thermoluminescence- peak around 180, 275, and 285 °C, respectively. This study showed that rare earth added $\text{Sr}_2\text{P}_2\text{O}_7$ materials can be promising material for dosimetric applications.

In the third part of this work, time saving microwave-assisted synthesis method was applied to produce pure LnBO_3 ($\text{Ln}=\text{La}$, Nd , Dy , Ho) by using urea and sucrose as a microwave active organic additive. For LaBO_3 and NdBO_3 , space group found as *Pnma* and for DyBO_3 and HoBO_3 powders crystallized in hexagonal unit cell with *P-6c2* space group. All microwave-assisted products have particle sizes lower than 1 μm .

In the final part of this study, pure LnBO_3 ($\text{Ln}=\text{Y}$, La , Nd , Sm , Eu , Gd , Dy , Ho , Er , Tm , Yb , Lu) powder samples were produced by using solid state reactions of Ln_2O_3 and H_3BO_3 (ratio=1:2) heated at 900 °C for 10 hours and 1000 °C for 5 hours. The crystallographic studies conducted with rietveld structural refinement and unit cell parameters, background functions, profile parameters, zero shift, atomic positions, and unisotropic thermal parameters were refined. LaBO_3 and NdBO_3 were solved based on *Pnma* orthorhombic structure while the crystal structure of YBO_3 , DyBO_3 and HoBO_3 were monoclinic *C2/c*. SmBO_3 showed triclinic *P-1* structure.

Keywords: XRD, Rietveld, Thermoluminescence, borates, phosphates, pyrophosphates, rare-earths, FT-IR, Raman, SEM.

ÖZ

YENİ NADİR TOPRAK ELELEMENTİ FOSFATLARININ SENTEZ VE KARAKTERİZASYONU VE NADİR TOPRAK ELEMENTİ ORTOBORATLARININ RİETVELD YAPISAL ANALİZİ

Bu çalışma, sodyum lantanit oksit fosfatların, nadir toprak elementi katkılanmış stronsiyum pirofosfatların sentez ve karakterizasyonu ile nadir toprak elementi ortoboratların Rietveld yapısal analizini kapsamaktadır. Hedeflenen malzemelerin sentezi için katı-hal ve mikrodalga-destekli sentez yöntemleri uygulandı. Sentezlenen bileşiklerin karakterizasyonu X-Işınları Toz Kırınımı (XRD), Infrared FT-IR, Raman, Taramalı Elektron Mikroskopu (SEM) yöntemleri kullanılarak yürütüldü. Rietveld Arıtım Yöntemi kullanılarak nadir toprak elementi ortoboratlarının yapısal analizi yapılmış ve üç boyutlu şekilleri saptanabildi.

Bu tezin ilk kısmında, bazı yeni sodyum lantanit oksit fosfatları Ln_2O_3 ($Ln= La, Nd, Sm, Gd, Dy, Ho, Er, Yb$), Na_2CO_3 , $NH_4H_2PO_4$ bileşiklerinin $1100\text{ }^\circ C$ 'de katı hal tepkimesiyle sentezlendi. Na_2LaOPO_4 , Na_2NdOPO_4 , ve Na_2SmOPO_4 bileşikleri *Pmm2* uzay grubuyla üretildi. Aynı prosedürle Na_2DyOPO_4 , Na_2HoOPO_4 , Na_2ErOPO_4 , and Na_2YbOPO_4 bileşikleri de literatürde ilk defa *Pmm2* uzay grubunda sentezlendi.

Tezin ikinci kısmında, literatürde ilk defa $\text{Sr}_2\text{P}_2\text{O}_7$ - ZrP_2O_7 katı çözeltisi katı kal yöntemiyle elde edildi ve karakterize edilip termolüminesans çalışmalarında kullanıldı. Bu çalışmalarda $\text{Sr}_2\text{P}_2\text{O}_7$ bileşiğinin 100 °C civarında ışımaya piki olduğu görüldü. Daha sonra saf $\text{Sr}_2\text{P}_2\text{O}_7$ bileşiğine CuO ve % 0.5-15 oranları (ağırlıkça) arasında bazı nadir toprak elementi oksitleri (Y_2O_3 , La_2O_3 , CeO_2 , Pr_6O_{11} , Nd_2O_3 , Sm_2O_3 , Eu_2O_3 , Gd_2O_3 , Tb_2O_3 , Dy_2O_3 , Ho_2O_3 , Er_2O_3 , Tm_2O_3 , Yb_2O_3 , Lu_2O_3) eklendi. XRD ile yapılan yapısal belirlemelerden sonra, termolüminesans çalışmaları, Cu ile birlikte $\text{Sr}_2\text{P}_2\text{O}_7$ bileşiğine eklenen Pr, Ho, Nd bileşiklerinde iki ışımaya piki olduğunu ve bu piklerden birinin her zaman 90 °C civarında ve diğerinin sırayla 180, 275, 285 °C derecelerde olduğunu ispatladı. Sonuç olarak bu malzemeler dozimetrik uygulamalarda kullanılacak malzeme adaydır.

Bu çalışmanın üçüncü kısmında, üre ve sukrozun yakıt olarak kullanıldığı zamandan kazanç sağlayan mikrodalga-yardımlı sentez yöntemi saf LnBO_3 ($\text{Ln}=\text{La}$, Nd , Dy , Ho) üretmek için uygulandı. LaBO_3 ve NdBO_3 , bileşikleri için uzay grubu Pnma olarak bulunmuştur. DyBO_3 and HoBO_3 toz bileşikleri hegzagonal birim hücre içinde P-6c2 uzay grubuyla kristallenmiştir. Microdalga-yardımlı üretilen tüm ürünlerin parçacık boyutunun 1 μm 'nin altında olduğu gözlemlendi.

Bu çalışmanın son bölümünde, saf LnBO_3 ($\text{Ln}=\text{Y}$, La , Nd , Sm , Eu , Gd , Dy , Ho , Er , Tm , Yb , Lu) toz numuneleri Ln_2O_3 ve H_3BO_3 (oran=1:2) bileşiklerinin 900 °C'de 10 saat ve 1000 °C'de 5 saat ısıtılmasıyla üretildi. Lantanit ortoboratların kristallografik çalışmaları Rietveld yapısal arıtımıyla yapıldı ve birim hücre parametreleri, taban fonksiyonları, profil parametreleri, sıfır kayması, atomik pozisyonlar ve isotropik olmayan termal parametreler arıtılmıştır. YBO_3 , DyBO_3 ve HoBO_3 bileşiklerinin kristal yapıları monoklinik C2/c sistemden oluşurken, LaBO_3 ve NdBO_3 bileşikleri Pnma ortorombik yapı esas alınarak çözüldü. SmBO_3 bileşiği triklinik P-1 yapıdadır.

Anahtar Kelimeler: XRD, Rietveld, Termolüminesans, boratlar, fosfatlar, pirofosfatlar, nadir toprak elementleri, FT-IR, Raman, SEM.

TO MY WIFE CEREN, TO OUR DAUGHTER DEFNE
AND TO MY FAMILY

ACKNOWLEDGEMENTS

The author wishes to express his deepest gratitude to his supervisor Assoc.Prof.Dr. Ayşen Yılmaz and co-supervisor Prof.Dr. Macit Özenbaş for giving the author the opportunity to conduct Ph.D. studies under their supervision. Sincere appreciation is especially for their guidance, comments, constructive criticism, encouragement, patience and insight throughout the research as well as leading the author to work independently.

It is great pleasure to thank my supervisor Assoc.Prof.Dr. Ayşen Yılmaz for her valuable guidance, support, advices for the completion of this work. She provided an academic environment of intellectual enrichment, advice and stimulation to excel and the lesson I learned under her guidance will serve me well in the future. I thank her very much for everything.

I would also like to thank the examining committee member Prof. Dr. Gülhan Özbayoğlu for her suggestions and comments during this study. I also wish to thank Prof.Dr. Ceyhan Kayran for her moral support and encouragement all the time.

I would like to express my thanks to Prof. Dr. Necmeddin Yazıcı for providing research facilities in Physical Engineering Department in Gaziantep University and extend my sincerest thanks for his great help in the thermoluminescence measurements, valuable comments and suggestions.

I would like to thank to Prof. Dr. Leyla Tatar Yıldırım and Assoc. Prof. Dr. Filiz Betül Kaynak from Hacettepe University and Prof.Dr. Orhan Büyükgüngör from Ondokuz Mayıs University for introducing the field of single crystal work and for their valuable discussion and friendship.

I wish to thank also Prof. Dr. Onuralp Yücel and Dr. Bora Derin from Adnan Tekin Ceramic Research Center of Istanbul Technical University for XRD measurements.

The author would like to thank to Prof. Dr. Barbara Albert for providing research opportunities in her laboratory at Eduard-Zintl Institut am Technische Universität Darmstadt, sparing time for discussions and fabulous comments. Special thanks are to Dr. Katrin Hoffmann, for fresh, energetic and enthusiastic way of approaching rietveld issues, invaluable help in refinement area to thesis, and a very friendly approach other than a supervisor. I wish to express my sincere thanks Gerd Bruhn for his help and patience in FTIR measurements. I also want to thank to Frederic Stober for his help during my Darmstadt visit.

Special thanks are to Michael W. Pitcher, for fresh, energetic, and enthusiastic way of approaching to issues, invaluable help to my research, and a very friendly approach.

The author would like to thank to ICDD (International Centre for Diffraction Data) for giving me scholarship to attend Advanced XRD Clinics Education. I would like to thank TUBITAK (107T181) for financial support to go to USA.

I am very grateful to my best friend Dr. Senem Kıralp Kayahan for her irreplaceable friendship, understanding, endless patience, continual support and being with me whenever I need and also her acquaintance at lunch.

I would like to give my special thanks to Prof. Dr. Levent K. Toppare for his inspiring discussions and wisdom for academia and life.

I wish to express my sincere thanks to Mehmet Kayhan and Tolga Depci for their help during the experiments and for their friendship. I wish to express my sincere thanks to Asli Tuba Taşkın for her help in academic search after I moved.

Colleagues from the neighboring groups, Görkem Günbaş, Yusuf Nur, Mehmet Zahmakıran, Asuman Durmuş, Nur Banu Öztaş, Abidin Balan, Simge Tarkuç, Aysel Kızıltay, Timur Karadağ and Yusuf Aktaş are kindly appreciated for sharing the depressing and cold environment of the D-block in the department. Appreciation is extended to colleagues in the Department of Chemistry, Middle East Technical University.

Words fail to express my eternal gratitude to my parents Fatma Bengi and Ömer Faruk Seyyidođlu and my brother Emin Ferhan Seyyidođlu, for giving me the intellectual and emotional guidance that made me who I am, and for their never-ending support, encouragement along with understanding for my frequent absences. This thesis could not have come to an end without their encouragement and tolerance.

Finally, my special thanks goes to my wife Ceren Obakan Seyyidođlu for her continuous support, love and patience to my long working hours, absence at weekends, sometimes weeks and for not leaving me alone in my stressful days. Without her none of this work could be accomplished.

I would like to thank METU for funding my thesis with the project number of BAP-01-03-DPT-03K-120920/09, BAP-2006-07-02-00-01, BAP - 2005-07-02-00-53, TUBITAK 107T181, TUBITAK 107M447.

CHAPTER 1

INTRODUCTION

1.1. Phosphates

For several reasons related to potential applications such as ionic conductivity or superconductivity, nonlinear optical properties, ferroelectricity, magnetism, laser properties, catalytic activity, etc., metal oxide phosphate compounds are still currently being investigated, i.e., KTiOPO_4 (KTP) (Miyamoto et al. 1995), NbOPO_4 (Moreno-Real et al. 1998), BiCoPO_5 (Ketatni et al. 1999), $\text{VOPO}_4 \cdot 3\text{H}_2\text{O}$ (Griesel et al. 2004), , $\text{Pb}_2\text{BiO}_2\text{PO}_4$ (Mizrahi et al. 1997), $\text{Bi}_{-6.2}\text{Cu}_{-6.2}\text{O}_8(\text{PO}_4)_5$ (Ketatni et al. 2003). Among these metal oxide phosphates, potassium titanium oxide phosphate KTiOPO_4 (KTP) crystals exhibit excellent nonlinear optical properties in the visible range, because of their high nonlinear coefficients and wide acceptance of temperature and angular fluctuations (Miyamoto et al. 1995). High thermal stability, good mechanical characteristics, transparency over a large wavelength range, large nonlinear optical coefficients, high damage threshold, and broad angular acceptance of KTP have made it the standard material for several industrial and medical applications (Bhaumik et al. 2002).

The structure of $\text{Li}_{(1-2x)}\text{Ni}_x\text{TiOPO}_4$ was resolved by Manoun et al. (2005) and they represented that the structure of the compositions $0 \leq x \leq 0.25$ is based on a three-dimensional framework constructed of chains of alternating TiO_6 octahedra and PO_4 tetrahedra, with the lithium and nickel atoms in cavities of the framework as shown in the Figure 1.1. KTP has an orthorhombic structure and belongs to the acentric point group $mm2$ (space group $Pna2_1$). Its structure consists of PO_4 tetrahedra and TiO_6 octahedra with potassium in larger voids. Ti-O bonds are short which are believed to be the prime cause of the nonlinear properties of KTiOPO_4 .

This family of compounds is generalized as $ABOXO_4$ where A may be K (Bhaumik et al. 2002), Rb, Ni (Jazouli et al. 1998), B may be Ti, Nb (Chani et al. 1997, Koseva et al. 2003, Moorthy et al. 1998), Nd (Sole et al. 1996), Sn, Mg (Chani et al. 1996), or a combination of two of these ions; X may be P, As (Chani et al. 1999).

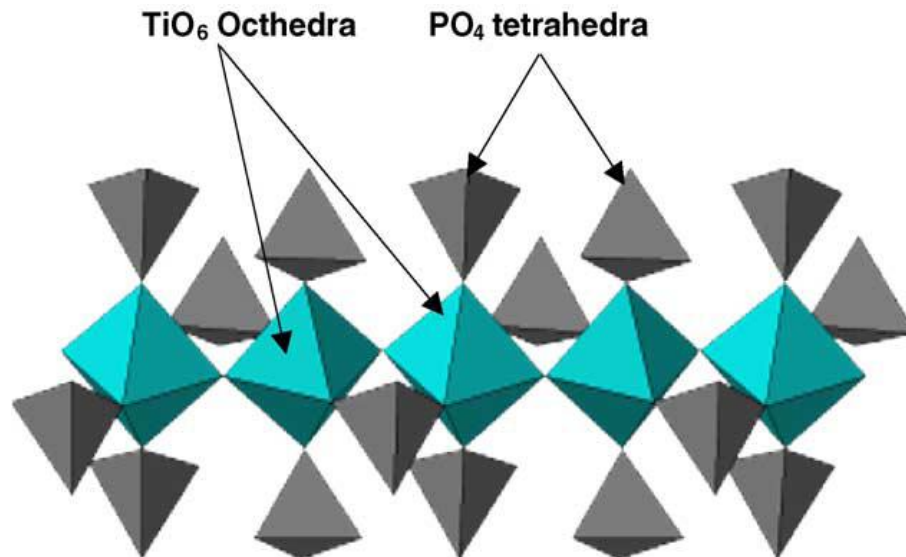

Figure 1.1. The structure of $Li_{(1-2x)}Ni_xTiOPO_4$ represented by Ti-O-Ti-O- chains (Manoun et al. 2005).

In the paper published by Carjaval et al. (2001, 2002), the effect of Er- and Yb- doping on the Nb:KTP crystals were investigated. As these materials seem promising materials for future research, KTP (Hu et al. 2003, Wang et al. 2002), many isostructural compounds are studied by large number of researchers. In the work done by Zhang et al. (2004), an effective blue coherent laser was obtained using Ce:KTP crystals. Kling et al. (2004) and Zaldo (1999) coworkers studied photoluminescence properties of Er- and Nd- implanted KTP and RTP crystals and the optical absorption of Nd^{3+} in KTP single crystals and in those co-doped with Al, Na and W have been studied (Zaldo et al. 2000, Zaldo et al. 1998). In addition to these, many research group worked on the mechanical (Stus et al. 2004), and optical

properties of KTP, RTP and Nb:KTP (Roth et al. 2004, Roth et al. 2001, Liu et al. 2000, Zhang et al. 2000).

As lanthanide phosphates ($LnPO_4$) have a wide range of potential applications for optical materials, including laser, phosphors, and more recently, anti UV-materials either in the form of powders, coatings or dense sintered parts, they have become of growing interest during the past few years and numerous researchers have been devoted to these compounds recently (Hirai et al. 2004, Schwarz et al. 1998, Kloss et al. 1997, Schwarz et al. 1997). Champion's group has reported the synthesis, characterization (Lucas et al. 2004a) and thermal (Lucas et al. 2004b) behaviour of $LnPO_4 \cdot H_2O$ while Onada (Onada et al. 2002) and coworkers have synthesized $LnPO_4 \cdot H_2O$ by using lanthanides where $Ln = La, Ce, Nd$; and oxide, carbonate, chloride, nitrate, sulphate, oxalate and fluoride as an anion.

While lots of reports present in the literature dealing with the synthesis, characterization and the properties of KTP and related materials, there are only few reports regarding the preparation of lanthanide oxide phosphates, some of which possesses KTP-type structure. A research performed by Kizilyalli' research group showed the presence of two orthorhombic lanthanide oxide phosphates i.e., Na_2GdOPO_4 (Gönen et al. 2000) and Na_2LaOPO_4 (Uztetik-Amour et al. 1995). However no attempt for the syntheses of other sodium lanthanide oxide phosphates has yet been reported in the literature.

1.2. Pyrophosphate

Pyrophosphates are technologically important materials due to their applications as ceramic, catalysts, ion exchange and optical materials. Because of their potential applications, many researchers synthesized either single crystal or powder pyrophosphates. The pyrophosphates were found in literature containing different formula group. Among these, one is $M^{IV}P_2O_7$ (M^{IV} is tetravalent), and the other is $M^{II}P_2O_7$ (M^{II} is divalent), and $M^I M^{III}P_2O_7$ (mixed valance).

The cubic ZrP_2O_7 is one of the most known pyrophosphate in $\text{M}^{\text{IV}}\text{P}_2\text{O}_7$ type. Symmetry characterization of cubic ZrP_2O_7 was studied by Withers et al. (2001) and Khorsvani et al. (1996) investigated unusual P-O-P bond angles in cubic ZrP_2O_7 . The phosphate tetrahedra connected to zirconium octahedra in ZrP_2O_7 structure was represented by Khosrovani et al. (1996) and given in Figure 1.2. The crystal structure of novel cubic pyrophosphate WP_2O_7 was reported in Lisnyak et al. (2000). Phase transition studies of pseudocubic SnP_2O_7 was published by Gover, Withers and coworkers (Gover et al. 2002).

Figure 1.2. The phosphate tetrahedral and a zirconium octahedron for ZrP_2O_7 structure (Khorosvani et al. 1996).

In the second formula group, the $[\text{P}_2\text{O}_7]^{4-}$ group containing divalent metals are given. Triclinic tin (II) pyrophosphate $\text{Sn}_2\text{P}_2\text{O}_7$ single crystals were obtained in argon flow in Shpanchenko's group (Chernaya et al. 2005). Another divalent metal containing triclinic pyrophosphate was obtained by Guler and Kurtulus (2005). They have followed microwave-assisted route to synthesize $\text{Pb}_2\text{P}_2\text{O}_7$. Besides these divalent metal containing pyrophosphates, Smaalen's group synthesized orthorhombic vanadyl pyrophosphate $(\text{VO})_2\text{P}_2\text{O}_7$ by heating $\text{VO}(\text{PO}_4) \cdot 0.5\text{H}_2\text{O}$ under argon atmosphere (Smaalen et al. 2005).

The mixed valance metal containing group is the largest member of pyrophosphates. Kızılyallı et al. (1993) synthesized orthorhombic NaGdP_2O_7 by using solid state reaction and orthorhombic HGdP_2O_7 (Kızılyallı 1987) by precipitation methods. Similarly, tetragonal NaDyP_2O_7 (Tie et al. 1997), orthorhombic NaLaP_2O_7 (Ferid et al. 2004a), monoclinic NaEuP_2O_7 (Ferid et al. 2004b), and orthorhombic KYP_2O_7 (Hamady et al. 1994) were obtained by many researchers. Single crystals of $\text{K}_2\text{SrP}_2\text{O}_7$ (Trunov et al. 1990), $\text{Rb}_2\text{SrP}_2\text{O}_7$ and CsSrP_2O_7 were synthesized by Trunov et al. (1991). They synthesized monoclinic LiMoP_2O_7 (Ledain et al. 1996) single-crystals by controlled cooling. Same procedure was applied and triclinic $\text{PbFe}_2(\text{P}_2\text{O}_7)_2$, monoclinic $\text{BaFe}_2(\text{P}_2\text{O}_7)_2$, and $\text{CuFe}_2(\text{P}_2\text{O}_7)_2$ were produced by Bouffessi et al. (1996a, 1996b). Another kind of diphosphate materials with the general formula RbLnP_2O_7 (where Ln= Dy, Ho, Y Er, Tm, Yb) (Khay et al. 2001a), CsLnP_2O_7 (where Ln= Gd, Tb, Dy, Ho, Y Er, Tm, Yb) (Khay et al. 2001b), and $\alpha\text{-Ca}_2\text{P}_2\text{O}_7$, CaCuP_2O_7 , SrCuP_2O_7 , SrCdP_2O_7 , BaMgP_2O_7 (Idrissi et al. 2004) have been deal of many studies. Hydrothermal synthesis of monoclinic $\text{Na}_2\text{CrP}_2\text{O}_7 \cdot 0.5\text{H}_2\text{O}$ was achieved by Stock et al. (2000). A new, dicationic, and acidic orthorhombic KHMgP_2O_7 was obtained by Assaaoudi et al. (2005). A series of compounds $(\text{M}^a_{0.5}\text{M}^b_{0.5})\text{P}_2\text{O}_7$, $\text{M}^a\text{M}^b = \text{AlTa}, \text{FeTa}, \text{GaTa}, \text{InNb}, \text{YNb}, \text{NdTa}$, and BiTa that are close structural relatives of cubic ZrP_2O_7 were prepared by Varga et al. (2005).

There were very few publications in literature about the properties of zirconium and strontium pyrophosphates. Emission spectra of ZrP_2O_7 activated with Eu^{3+} and Tb^{3+} were investigated by Pelova and Grigorov (1997) and dielectric properities of ZrP_2O_7 was investigated by Kim and Yim (1999). Besides these, zirconium pyrophosphates are used as catalyst in n-butane oxidative dehydration (Marcu et al. 2002) and used as a new packing material for high performance liquid chromatography (Inoue and Ohtaki 1993). Prasad and coworkers investigated preparation and ammoxidation functionality of zirconium phosphate-supported V_2O_5 catalysts (Srilakshimi et al. 2006).

Also, crystal structure and phase transitions of strontium zirconium diorthophosphate, $\text{SrZr}(\text{PO}_4)_2$, was published recently (Fukuda et al. 2004) while europium-ion doped strontium pyrophosphate and its photoluminescence work was done by Natarajan et al. (2004). Semiconductive properties of Ti and Zr pyrophosphate catalysts were studied by Marcu et al. (2002). Amezawa's work (2005) was based on high temperature protonic conduction in $\text{Sr}_2\text{P}_2\text{O}_7$ - LaPO_4 system.

Luminescent applications of pyrophosphates are subject of many research groups. The allotropic forms and photoluminescent properties of europium-doped calcium pyrophosphates were described by Doat et al. (2005) while Schipper et al. (1994) examined luminescence of hafnium pyrophosphate which emit in the UV spectral range. Recently, the crystal structure and luminescence spectra of new potassium erbium pyrophosphate dihydrate $\text{ErKP}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$ were published by Assaaoudi et al. (2006). Ce-doped luminescence of first lutetium diphosphate $\text{NH}_4\text{LuP}_2\text{O}_7$ was shown by Li et al. (2005).

Thermoluminescence properties of pure and doped strontium pyrophosphates were demonstrated by various scientific research groups because the rare earth activated inorganic phosphors are widely used in a variety of applications, such as lamp industry, color display, radiation dosimetry and X-ray imaging (Natarajan et al. 2004). The emission of Eu^{2+} ions varies from blue to red depending on the host lattice due to crystal-field effects. Eu^{2+} activated strontium pyrophosphate is considered to be a potential candidate for use in lamps for photo-therapy of hyperbilirubinemia (infant jaundice), since its emission is at 420 nm with negligible contribution from ultra-violet radiation; and hence, will be safe for treating infants. In fact, Eu^{2+} and Mn^{2+} co-doped $\text{Sr}_2\text{P}_2\text{O}_7$ has been suggested as one of the potential phosphors, to be used in the phosphor mixture for obtaining white light emission from UV - LED devices (Srivastava 2003). The solid solution of ZrP_2O_7 - $\text{Sr}_2\text{P}_2\text{O}_7$ was synthesized and the thermoluminescence properties of these solid solutions were examined (Seyyidoglu et al. 2007).

1.2.1. Thermoluminescence

It is possible to define the phenomenon of thermoluminescence (TL) in several different ways, one of which is emission of light when a material is heated. Yet, in the details of the mechanism the definition gets a bit more complicated. Mahesh et al. (1989) described the thermoluminescent phosphors as materials that keep the energy given by a pre-excitation by an appropriate type of radiation, ultraviolet, nuclear or cosmic waves, within itself. Then, when the luminescent object is subjected to heat up to a certain temperature which triggers the release of energy, it is possible to observe emission of this energy as visible light. Thermoluminescent materials are used in radiation dosimetry (clinical, radiotherapy, personnel) (Cuong et al. 2004) and are functional in archeological and geological dating.

Thermoluminescent materials find wide spread use in industry in two different areas which are further divided into subgroups. First major area of thermoluminescence is the “radiation dosimetry”. Radiation dosimetry is the measurement and/or calculation of the absorbed dose from an exposure to ionizing radiation in tissue and in matter. Secondly, thermoluminescence properties of materials are beneficial in dating of archeological and geological samples that includes complications compared to radiation dosimetry (Chen and Mckeever 1997, Mahesh et al. 1989, Pradhan 1981).

1.3. Borates

Boron, which is semi-metallic element with an atomic number of 5, does not occur in nature as free element due to its unstable nature in elemental form. There are more than 230 borate minerals (Kistler et al. 1994). Commercial boron mineral deposits are distributed globally in the following areas depending on the appropriate combination of the volcanic activity and the climate for example in South West USA Mojave Desert, Turkey and South America Andean Belt.

The world's largest borate reserves occur in Turkey in Western Anatolia, South of the Marmara Sea within an area roughly 300 km east-west by 150 km North-south. The main borate districts in Turkey are Bigadiç, Kestelek, Sultançayırı, Emet and Kırka (Kistler and Helvacı, 1994). Turkey is the largest producer of natural borates in the world. The only producer of the borates in Turkey is the government owned ETİ Mine Works. The other countries in the world who produce boron are United States, Russia, Kazakhstan, Argentina, China, Peru and Chile.

Table 1.1. World Boron Reserves (Roskill, 2002)

Country	Total Reserve (Million Tons)	%
Turkey	563	64
USA	80	9
Russia	100	11
China	36	4
Chile	41	4
Bolivia	15	2
Peru	22	3
Argentina	9	1
Kazakhstan	15	2
TOTAL	885	100

Turkey is the world's major source of colemanite. Ulexite is found mainly in Turkey, Andes of South America and China. The total world reserves are 885 million tons (Grand total including proven, probable and possible reserves) on B₂O₃ basis with the following shares given in Table 1.1. (Roskill, 2002).

Borates and borate derivatives find an unusually large range of uses today. The principal application area of borates is the glass industry which is accounting for an estimated 43% of the total world borate consumption (Roskill, 2002). Detergent and the enamel, frit, glaze areas follow the glass industry. The other usage areas of

the boron compounds are in agricultural purposes, fertilizers, wood preservation, flame retardants, abrasives, herbicides, pharmaceuticals, nuclear applications, metallurgical fluxing, photography, textile finishing, armour protection, advanced composites, abrasives, cutting edges, nuclear weapons, catalysts, electronic components, purifying chemicals, cleaning chemicals, hydrogen cells (Roskill, 2002).

1.3.1. The Crystal Structure of Borates

The crystal chemistry of borates and the structural systems of its basis differ from those for silicates, phosphates, sulfates, carbonates, nitrates since anionic groups in the borate class can be both B-tetrahedra and B-triangles (Belokoneva 2005). Investigation of the phase diagrams of borate systems has resulted in the synthesis of about 600 anhydrous borates, borosilicates and their structural derivatives (Leonyuk et al. 1983). Most of these borates melt incongruently and borate melts have a high viscosity because of their tendency to form various complex polyanions of different composition and configuration.

In recent years more and more research has been concentrated on borate crystals since the possibility of wide isomorphous substitutions one can consider these borates as polyfunctional materials with device potential. Generally, the structure of anhydrous borates is characterized by a variety of discrete and condensed BO_3 and BO_4 anions. Predominant structures among borates, especially binary and more complex borate groups are isolated BO_3 triangles (about 65%) (Leonyuk 1997).

Yuan and Xue (2007) have worked on the classification and the algebraic description of crystal chemistry of borates are given by topological type of fundamental building blocks. The 70-year history of borate structure determinations has illustrated the unique chemistry of borates, characterized by the following distinguishing features (Becker, 2001; Filatov & Bubnova, 2000; Touboul et al., 2003):

- (i) In borate crystal structures, the B atoms can have both three $[B\phi_3]$ and four $[B\phi_4]$ coordinations to oxygen or hydroxyl groups ($\phi = O^{2-}, OH$),
- (ii) Both $B\phi_3$ triangles and $B\phi_4$ tetrahedra can be connected to each other.
- (iii) FBBs can polymerize into complex borate polyanions such as those with infinite chains, layers and network anions.

1.3.2. Rare Earth Orthoborates

Many compounds containing rare-earths are good candidates for applications in laser and luminescence materials, but the emission is often quenched by doping ion interactions over a critical concentration. The quenching phenomenon is reduced when active ions are separated by the large anions such as PO_4 , WO_4 . Specially, rare-earth borate compounds present a great structural complexity because boron atoms can form planar or nonplanar BO_3 groups, where three oxygen atoms form sp^2 hybrids, and also tetrahedral BO_4 groups, where four oxygen atoms form sp^3 hybrids (Chinn and Hong 1976).

During the past few years, much interest has been devoted to the study of yttrium and lanthanide orthoborates because of their high UV transparency and exceptional optical damage threshold, that make them attractive for numerous applications. In the last couple of years considerable effort has been given to improve the performance of these materials (Veenis and Bril, 1978). So, improving the performance, as well as any sensible interpretation of the luminescent properties, requires a well-defined crystal structure of these compounds (Ren et al. 1999).

Various methods have been developed to prepare high-quality $LnBO_3:Eu$ phosphors, such as solid-state reaction (Lemanceau et al. 1999, Zhang et al. 2008), coprecipitation method (Lemanceau et al. 1999, Kim et al. 2002), combustion synthesis (Tukia et al. 2005), ultrasonic spray pyrolysis (Kim et al. 2000), sol-gel technique (Boyer et al. 2001, Boyer et al. 1999, Zhu et al. 2008) and sol-gel pyrolysis process (Wei et al. 2002a, Wei et al. 2002b).

In Klassen's (Klassen et al., 2005) research, lutetium and yttrium borates doped with europium, terbium, gadolinium, etc., have been produced by dissolving initial oxides and nitrates in ammonium nitrate melt and thermal decomposition of the solvent. Three methods were employed to prepare the red phosphor (Y,Gd)BO₃; coprecipitation-combustion method, salt assisted combustion method and emulsion method by Cui et al. (2008). Powder samples of YBO₃:Eu³⁺ were prepared using either the conventional solid-state reaction, or soft routes such as wet process or sol-gel method starting with alkoxides precursors by Boyer et al. (2003).

A number of studies have been devoted on hydrothermal synthesis of LnBO₃, and LnBO₃ nanoparticles or LnBO₃ with specific morphologies were obtained (Li et al. 2006, Jiang et al. 2004a, Kim and Kang 2005, Jiang et al. 2003, Jiang et al. 2004b, Zhang and Lin 2004, Yang et al. 2008). For example, Jiang et al. (2003) have prepared YBO₃:Eu nanoparticles (particle size; 20 nm) by a hydrothermal method in the presence of urea. Jiang et al. (2004b) have reported the formation of donut-like assembly of YBO₃:Eu crystals by the hydrothermal method under an alkaline condition. Y_{1-x}BO₃:Nd_x nanoparticles prepared by mild hydrothermal synthesis and found to be isostructural with YBO₃ crystal (PDF#16-277) by Wang et al. (2004a). Wang et al. (2006) also synthesized Vaterite-type Y_{1-x}Tb_xBO₃ phosphors using hydrothermal synthesis method. Zhang and Lin (2004) have reported that YBO₃:Eu crystals with flower-and hedgehog fungus-like structures synthesized by the hydrothermal method under acidic conditions.

Beside the luminescent properties, the different material properties of rare earth orthoborates have been also examined by several groups. Amezawa et al. (2004) have reported the high temperature protonic conduction in 1 mol %Sr doped LaBO₃. Laser absorbance studies of samarium borate was investigated by Huili et al. (2007). The nanosize lanthanide borates were also investigated. Lanthanum borate nanowires have been fabricated by reacting lanthanum oxide and boron with carbon nanotubes at 1100 °C (Lin et al. 2007).

Lanthanide orthoborate, LnBO_3 , is compositionally the simplest of the compounds in the $\text{Ln}_2\text{O}_3\text{-B}_2\text{O}_3$ systems. Yet, the crystal structure determination has been far more complicated. Although numerous efforts have been given to the structure determination, there are still considerable controversies left. Levin et al (1961) have investigated their polymorphism and reported on the regions of stability of the different structures in relation with borates preparation temperature and the ionic radius of the rare earth compounds. They showed that the structures of the rare earth borates are related to the three crystalline forms of CaCO_3 , aragonite, vaterite, and calcite, depending on the rare earth. The orthoborates of the light rare earths (La to Nd) exhibit the aragonite-type structure and those of the heavy rare earths (Sm to Yb) possess the vaterite-type structure.

Many of aragonite type rare earth borates reported for LaBO_3 (Nakatsuda et al. 2006, Gornuyova 2003, Tukia et al. 2005), NdBO_3 (Müller-Bunz et al. 2003, Gornuyova 2003, Laureiro et al. 1990), CeBO_3 (Goubin et al. 2004). Aragonite type rare earth orthoborates (PrBO_3 , SmBO_3 , EuBO_3) were also synthesized by Meyer (1969) and Laureiro et al. (1991). The crystal structure of aragonite type LaBO_3 were explained first time by Abdulaev et al. where he investigated space-group setting as Pmcn (1976). The aragonite- and calcite-type orthoborates contain triangular BO_3^{3-} groups confirmed by both X-ray diffraction and spectroscopic studies (Levin et al. 1961, Antic-Fidancev et al. 1992, Bohlhoff et al. 1971).

In Gornuyova's PhD Thesis (2003), the projection of the structure of LaBO_3 (Aragonite-Type) parallel to $[010]$ and the coordination polyhedra of La-Atom in the structure of LaBO_3 (Aragonite type) were well defined and shown in Figure 1.3. and Figure 1.4., respectively. In Figure 1.3., it is obviously seen that trigonal planar $[\text{BO}_3]$ surrounds nine coordinated La atoms. As shown in Figure 1.3., the La atom is coordinated by nine O and the B atom is planar-triangularly coordinated by three O atoms. Each LaO_9 polyhedron shares edges with six other LaO_9 polyhedra and three BO_3 triangles, whereas each BO_3 triangle shares edges with three LaO_9 polyhedra.

The representation of the aragonite-type LT-LaBO₃ structure with LaO₉ groups is given in Figure 1.5. (Nakatsuka et al. 2006).

Figure 1.3. The projection of the structure of LaBO₃ (Aragonite-Type) parallel to [010] (Gornuyova, 2003)

Figure 1.4. The coordination polyhedra of La-Atom in the structure of LaBO₃ (Aragonite-type) (Gornuyova, 2003)

Figure 1.5. Representation of the aragonite-type LT-LaBO₃ structure. LaO₉ groups are shown as hatched polyhedra and B atoms as black spheres. B-O bonds are indicated as solid black lines (Nakatsuka et al. 2006).

Meyer and Skokan (1971) have obtained YbBO₃ in calcite structure. The structural analysis of single crystal LuBO₃ and single crystal structural analysis of YbBO₃ were done by Abrahams et al. (1971) and Hupertz (2001), respectively. The space group of them is R-3c symmetry. The octahedral coordination of Lu-atoms and isolated trigonal [BO₃] groups were shown in Figure 1.6.

Figure 1.6. The structure of calcite type rare earth orthoborate (Abrahams et al. (1971).

Although most of the anhydrous rare earth borate phases have been known for quite a long time, many controversies about the structures and even the composition remained to be clarified. For example, Corbel et al.(1999) have revised the crystal structure of EuBO_3 and assigned it to the space group $P-1$, similarly to the findings of Palkina et al.(1976) for the case of low temperature SmBO_3 . Triclinic DyBO_3 and ErBO_3 single crystals with $P-1$ space group were obtained by Huppertz et al. (2002) using high-pressure synthesis. Meyer (1972) obtained triclinic rare earth orthoborates LnBO_3 ($\text{Ln}=\text{Pr, Nd, Sm, Eu, Gd, Tb, Dy}$). Colourless single crystal rods of triclinic ($P-1$) DyBO_3 and triclinic ($P-1$) single crystals of NdBO_3 were synthesized by Emme and Huppertz (2004) and Noirault et al. (2006) respectively. The structure of triclinic SmBO_3 were given in Gornuyova's work (2003) in Figure 1.7. In this figure, it is obvious that structure has $[\text{BO}_3]$ group around cationic polyhedra. In Figure 1.8., the $[\text{SmO}_8]$ polyhedra in triclinic SmBO_3 structure (Gornuyova, 2003).

In the structure of SmBO_3 , the rare earth atoms occupy the centres of distorted SmO_8 triangulated dodecahedra (Figure 1.8.). Each dodecahedron shares edges with four others to build infinite double chains and also The isolated threefold coordination of boron is regular.

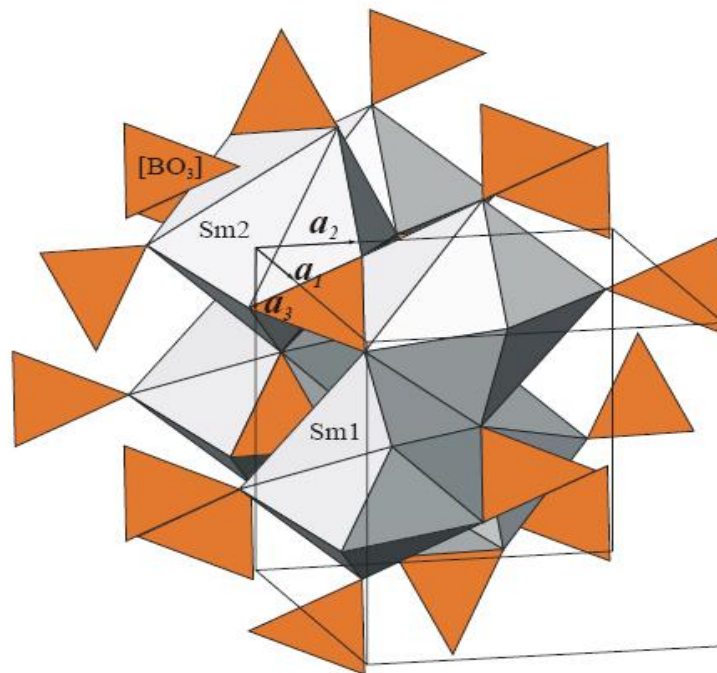

Figure 1.7. The structure of triclinic (P-1) SmBO_3 (Gornuyova, 2003).

Figure 1.8. The $[\text{SmO}_8]$ polyhedra in triclinic SmBO_3 structure (Gornuyova, 2003)

For the vaterite-type compounds (Sm to Yb), Newnham et al.(1963) have proposed two possible structure models, a disordered hexagonal ($P6_3/mmc$) structure and an ordered hexagonal ($P6_3/mcm$) structure. Bradley et al. (1966) and Cohen-Adad et al. (2000) described the structure using the $P-6c2$ space group. A common feature of these models is that the borate group was assumed to be in triangular geometry (BO_3^{3-}). Later IR, NMR, and Raman studies (Laperches and Tarte 1966, Denning and Ross 1972, Kriz and Bray 1969) however, revealed that these compounds contain only the tetrahedral polyborate group of $\text{B}_3\text{O}_9^{9-}$.

Many researchers have synthesized different vaterite type of LnBO_3 compounds using several techniques. Tugia (2005) and coworkers have prepared vaterite type YBO_3 and GdBO_3 . Felten (1961) prepared rare earth borates (Y, Sm, Eu, Gd, Dy, Ho, Er, Tm, Yb, Lu) of ABO_3 type by the reaction of the constituent oxides in equimolar ratios between 1200 and 1400 °C in air and he observed that the borates of yttrium and smaller rare earth ions (samarium through lutetium) are isostructural with vaterite type CaCO_3 . In Henkels and Schaak's (2008) work, LnBO_3 (Ln=Y, Nd, Sm, Eu, Gd, Ho) and $\text{YBO}_3\text{:Eu}$ nanocrystallines were synthesized using a borohydride-based solution precursor route and they presented that they found vaterite structure for LnBO_3 orthoborates. Hosokawa et al. (2008) prepared YBO_3 with space group $P6_3/m$ by using the glycothermal reaction of the rare earth acetate with trimethoxyborane (Ln/B=1) at 315 °C for 2h.

Since yttrium borate compounds have luminescent properties with rare earths, many researcher tried to synthesize this compound by using different techniques. Yttrium orthoborate crystallizes in the vaterite-type structure and has two polymorphic forms, a low and high temperature one. Plewa (2007) and Jüstel have studied the phase transition of YBO_3 and found that the true LT-HT (low temperature to high temperature) transition temperature is 987 °C while HT-LT transition is seen around 558 °C (Plewa et al. 2007). Single phase YBO_3 (PDF#88-0356, $P6_3/m$) is obtained at the pH 5-6. (Tkachenko et al. 2007).

In Beregi's (Beregi et al. 2002) work, vaterite type LnBO_3 (ICDD files for Yb-, Er-, Ho-, Gd- and Y- borates: 19-1427, 13-486, 13-478, 13-483 and 16-277, respectively) were synthesized. YBO_3 pseudo-vaterite structure ($P6_3/m$) in Chadeyron et al. (1997b). Chadeyron et al. (2001) prepared vaterite YBO_3 and H-LnBO_3 ($\text{Ln}=\text{La, Nd, Sm, Eu}$) orthoborates by sol-gel mineral process. Chadeyron et al. (1997a) reinvestigated the crystal structure of YBO_3 and found that the structure contains the $\text{B}_3\text{O}_9^{9-}$ group. They described the structure in a hexagonal cell with the space group $P6_3/m$. In their structure model, the boron position and one oxygen position are partially occupied. The structure YBO_3 plane is given in Figure 1.9.

Figure 1.9. Projection of the structure of YBO_3 on the (001) plane (Chadeyron et al. 1997a)

With respect to the large anion size, it is unlikely that the $\text{B}_3\text{O}_9^{9-}$ group is rotationally distorted in this solid-state structure. Yet, the structure model they proposed provides a reasonable basis for the structure of the vaterite type. The structure and the sketch of $\text{B}_3\text{O}_9^{9-}$ ion were given in Figure 1.10.

Figure 1.10. a) The Structure of $\text{B}_3\text{O}_9^{9-}$ (Wang et al. 2006), b) Structural sketch map of $\text{B}_3\text{O}_9^{9-}$ ion (Wei et al. 2002a).

By using powder X-ray and electron diffraction techniques, Ren et al.(1999) have found super-reflections corresponding to a rhombohedral cell, $a=6.6357 \text{ \AA}$ and $c= 26.706 \text{ \AA}$ with space group $R\bar{3}2$, for GdBO_3 but the proposed structure model was also questioned for its unphysical bond distances. In this work, Ren et al.(1999) have employed all of the possible space groups ($R\bar{3}$, $R\bar{3}2$, $R\bar{3}2$, $R\bar{3}m$, or $R\bar{3}m$) for constructing the structure model and only $R\bar{3}2$ led to a reasonable solution. The structure defined here was refined by using the Rietveld technique and the boron atoms cannot be identified from the refinement because their scattering power is too small. They were inserted into the structure by considering the structure of the polyborate group $\text{B}_3\text{O}_9^{9-}$. The B_3O_9 sheet in the $R\bar{3}2$ structure of LT phase of GdBO_3 is given in Figure 1.11.

Figure 1.11. The B_3O_9 sheet in the structure of LT phase of GdBO_3 (Ren et al. 1999)

The crystal structure of LT phase of GdBO_3 with unit cells $a=6.6357 \text{ \AA}$ and $c=26.706 \text{ \AA}$ is shown in Figure 1.12.

Figure 1.12. The crystal structure of LT phase of GdBO₃ (Ren et al. 1999)

Parallel efforts to characterize the vaterite-type rare earth orthoborate have been undertaken through the spectroscopic investigations. Yet, the high resolution luminescence spectra revealed a difficulty in distinguishing between the alternatives of having either two (Hölsa 1987, Chadeyron et al. 1997b) or three (Boyer et al. 2003) cation sites in the structure. In order to clarify the structures of the vaterite-type rare earth orthoborates, one needs to use a special technique that is more sensitive to light atoms.

Lin et al. (2004) reported the use of neutron diffraction as a complementary structure solution tool, since the coherent elastic scattering lengths of rare earths, oxygen, and boron for neutrons have the same order of magnitude. In their work, they have solved the low and high temperature modifications. The low temperature polymorph crystallizes in a C-centered monoclinic cell with $C2/c$ space symmetry, the unit cell parameters being $a=11.3138(3)$ Å, $b=6.5403(2)$ Å, $c=9.5499(2)$ Å, and $\beta=112.902(1)^\circ$. The boron atoms in the structure are all tetrahedrally coordinated and form the three-membered ring borate B_3O_9 moiety. The high temperature polymorph also crystallize in $C2/c$ space symmetry but the borate groups in the high-temperature structure are all isolated flat BO_3 triangles. In Figure 1.13., the projection of the low temperature structure of monoclinic YBO_3 along b axis, along (001) direction were given.

Figure 1.13a illustrates a projection of the crystal structure of the low-temperature phase of $(Y_{0.92}Er_{0.08})BO_3$ vaterite along the b -axis. The structure could be described as alternative stacking of cation sheets and borate layers. The boron atoms are all tetrahedrally coordinated in the BO_4 units, which share vertices, thus forming three membered ring borate B_3O_9 units. Figure 1.13b presents the structure projected along the (001) direction. It can be seen that the yttrium atoms adopt the layers of the almost ideal close-packed arrangement.

In Li's (Li et al. 2008) work, the environmental factors are computed and the corresponding LMCT (ligand-to-metal-charge-transfer-) energies of Eu^{3+} are predicted from space groups $P-6c2$ and $C2/c$ of the orthoborate YBO_3 based on the dielectric theory of the complex crystal. The result shows that only the space group $C2/c$ proposed by Lin et al. (2004) is in good agreement with the experimental phenomena.

Figure 1.13. (a) Projection of the structure of the low-temperature phase $(Y_{0.92}Er_{0.08})BO_3$ along the b -axis. (b) Projection of the structure of the low-temperature phase $(Y_{0.92}Er_{0.08})BO_3$ along the (001) direction. (Lin et al. 2004).

1.4. X-ray Diffraction Structure Determination and the Rietveld Structure Refinement Analysis

1.4.1. The Renaissance of Powder Diffraction

The method of X-ray powder diffraction was devised independently in 1915 by Debye and Scherrer in Germany and in 1916 in the United States, and initially relied on photographic film record the angles and intensities of the diffracted beams. When properly employed, powder diffraction can yield a great deal of structural information about the material under investigation. A given substance always produces a characteristic diffraction pattern. This fact is the basis for the diffraction method of chemical analysis. The powder pattern of a substance is characteristic of that substance and forms a sort of fingerprint by which the substance may be identified (Cullity and Stock, 2001).

Although the diffraction of X-rays from powders (microcrystalline samples) had been discovered by Max von Laue shortly after his historical experiment on a single-crystal of KCl (which he crushed, on purpose, to verify his fresh hypothesis on the nature of such experiment), the Powder Diffraction technique has been seldom

used as a structural tool at the beginning. For more than 50 years powder became a widespread analytical method for the characterisation of soils, ores, rocks, metals, alloys, and, more recently, ceramics, drugs, plastics, dyes and other commodities since it is very clear that powder traces could be used as fingerprints in qualitative analysis of crystalline materials of different origins (Masciocchi, 1997).

At least in principle, every crystalline material shows a unique X-ray diffraction pattern. The potential for qualitative phase identification was certainly recognized from the early days of X-ray diffraction. The most significant milestone of X-ray phase analysis is creating X-ray diffraction databases. Today, the file is produced in annual updates by the International Centre for Diffraction Data (ICDD), which is a nonprofit corporation relying on the volunteer efforts of many of the powder diffractionists. Beside the main ICDD database, there are several other databases for structural studies. The crystallographic and structural information can be obtained from Cambridge Structural Database (CSD) for organic and organometallics, Inorganic Crystal Structure Database (ICSD) for inorganic materials, NRCC Metals Data File for the structure of macromolecules, NIST Crystal Data for inorganic and organic unit cells (Jenkins and Synder, 1996).

1.4.2. Rietveld Theory

The Rietveld (Rietveld 1967, 1969) method refines user-selected parameters to minimize the difference between an experimental pattern (observed data) and a model based on the hypothesized crystal structure and instrumental parameters (calculated pattern). By using Rietveld refinement background profile, atomic parameters, unit cell parameters, unit cell axes, atomic positions, etc. can be refined and three dimensional crystal structure can be finally drawn.

The quality of the Rietveld refinement fit (ie. the quantitative measure of the matching between observations and the calculated pattern), which should give information about the true values of all parameters in calculated model (for which an

estimated standard deviation, in the least-squares sense, is supplied), is normally evaluated by agreement factors, defined as:

$$R_p = \sum_i |y_{oi} - y_{ci}| / \sum_i |y_{oi}| \quad [\text{R-profile}]$$

$$R_{wp} = \sum_i w_i |y_{oi} - y_{ci}|^2 / \sum_i w_i |y_{oi}|^2 \quad [\text{Weighted R-profile}]$$

$$R_B = \sum_k |I_{ok} - I_{ck}| / \sum_k |I_{ok}| \quad [\text{R-Bragg}]$$

where i runs over all data points, and k runs over all (space-group permitted) reflections. Since I_{ok} (observed integrated intensities) are not readily available, a number of numerical algorithms, partitioning the observed intensities of overlapping peaks into their partial contributions have been developed.

From the above considerations, it is obvious that the Rietveld method requires digitised data and knowledge of an approximate structural model (ie., lattice parameters, space group symmetry and fractional atomic positions). A number of other starting parameters, mostly instrumental, can be guessed by visual inspection (background coefficients, zero angle, etc.) (Masciocchi, 1997).

1.4.2.1. The Rietveld Refinement Steps

For a Rietveld refinement, it is essential that the powder diffraction data be collected appropriately. Factors to consider prior to data collection and calibration are; the most suitable radiation (e.g. conventional X-ray, synchrotron X-ray or neutron), the wavelength, appropriate sample preparation and thickness, slit sizes, and necessary counting time (McCusker et al. 1999).

In order to be sure about counting statistics throughout a X-ray powder diffraction pattern, longer time should be spent on the data collection at high angles where intensities are lower. An ideal particle size within a powder sample is around 1-5 μm . Sample rotation will improve the particle homogeneity. Any trial to smooth the diffraction profile before doing a Rietveld refinement must be resisted.

Smoothing introduces point-to-point correlations which will give wrongly lowered e.s.d.'s in the refinement. After completing the necessities for sample scanning, Rietveld analysis is composed of the refinement of the following parameters (McCusker et al. 1999):

a) Background Correction: There are two approaches to dealing with the background in a powder diffraction pattern. Background can either be estimated by linear interpolation between selected points between peaks and then subtracted, or it can be modelled by an empirical or semiempirical function containing several refinable parameters.

b) Peak Shape Function: The peak shapes observed are a function of both the sample (e.g. domain size, stress/strain, defects) and the instrument (e.g. radiation source, geometry, slit sizes), and they change as function of 2θ . Among the analytical peak-shape functions investigated, the pseudo-Voigt approximation of the Voigt function is probably the most widely used X-ray and constant wavelength neutron data (Thompson et al. 1987). The pseudo-Voigt function can be described as a linear combination of Lorentzian and Gaussian components. This appears to describe the symmetrical part of an X-ray diffraction peak quite well.

c) Profile: If only a partial structural model is available, the calculated intensities may differ significantly from the observed ones, and this can complicate the initial refinement of profile parameters (changes in FWHM and peak asymmetry as a function of 2θ , 2θ correction, unit-cell parameters). In such a case, it is probably best to use a structure-free approach, in which the intensities of the reflections are simply adjusted to fit the observed ones (Le Bail et al. 1988), to obtain initial values for the profile parameters. This Le Bail refinement option, which can also be used to extract a list of integrated intensities from a powder pattern for structure determination, has now been included in most modern Rietveld programs.

d) Completing the Structural Model: In general, refinement of structural parameters should not be started before all (or almost all) atoms in the given structure have been found. Otherwise, refinement is likely to lead to a false minimum, because the algorithm will try to describe all of the electron density with too few atomic positions.

e) Refining the Structure: The Rietveld refinement of structural parameters can begin with a complete structural model and good starting values for the background contribution, the unit-cell parameters and the profile parameters. Because the global minimum of the least-squares residual function is much shallower with powder data than it is with single-crystal data, the refinement needs continuous monitoring. A refinement of a structure of medium complexity can require a hundred cycles, while a structure of more complex compound may easily require several hundred. Refinement is generally done in sets of two to five cycles at a time. In order to monitor the progress of a refinement, the two most useful pieces of information are the profile fit and the nature of the parameters shifts (i.e. shift/e.s.d: are the shifts oscillating, diverging or converging). The profile fit is best seen in a plot of the observed and calculated patterns, but can also be followed numerically with a reliability factor or residual, R, value.

1.4.2.2. Rietveld Programs

There are lots of commercial and free of charge Rietveld programs available. The commercial programs; i.e. Jade, High Score Plus, Topas are softwares of the XRD producer companies. Free of charge programs such as GSAS, Fullprof, EXPO, SIRWARE, QUANTO, BRASS, etc. can be easily downloaded from their web sites. GSAS and Fullprof software packages are most interested by universities and institutions.

1.4.2.2.1. GSAS Software Package (General Structure Analysis System)

GSAS is a set of programs for the processing and analysis of both single crystal and powder diffraction data obtained with X-rays or neutrons and the EXPGUI is the Graphical User Interface for the GSAS. It is capable of handling all of these types of data simultaneously for a given structural problem. In addition, it can handle powder diffraction data from a mixture of phases refining structural parameters for each phase (Larson and Von Dreele 2000, Toby 2001). By using GSAS in Rietveld refinements, unit cell parameters, background functions, profile parameters, zero shift, atomic positions, and unisotropic thermal parameters can be refined. At the end of refinement, GSAS can provide R_p , R_{wp} , χ^2 shift values and by using final data three-dimensional structure of refined compound can be drawn.

1.5. Purpose of the Thesis

The purpose of this thesis is to synthesize and characterize rare earth containing borates and phosphates, to investigate the crystallographic effect of rare earths on these compounds and to make Rietveld structural analysis for pure rare earth orthoborates. For this purpose, rare earth phosphates, rare earth added pyrophosphates and rare earth orthoborates were synthesized by using solid state reaction and microwave-assisted solid state reaction.

In the phosphate part of the thesis, we divided this group into two separate chapters both including different chemical reactions. In the first part, we synthesized sodium lanthanide oxide phosphates. Since there are only two sodium lanthanide oxide phosphates present in literature, we tried to synthesize other lanthanide oxide containing phosphates and produced $\text{Na}_2\text{SmOPO}_4$, $\text{Na}_2\text{DyOPO}_4$, $\text{Na}_2\text{HoOPO}_4$, $\text{Na}_2\text{ErOPO}_4$, and $\text{Na}_2\text{YbOPO}_4$ for the first time in the literature.

In the second part of the phosphates, the suitability of $\text{Sr}_2\text{P}_2\text{O}_7$ for its use in TL dosimetry was investigated since our literature survey indicated that the TL and dosimetric properties of rare earth added and pure $\text{Sr}_2\text{P}_2\text{O}_7$ samples have not been studied up to now. For this purpose, $\text{Sr}_2\text{P}_2\text{O}_7$ compound were prepared and rare earths and CuO added into the this compounds. For the characterization of the produced new phases, XRD, IR, and SEM methods were applied to see the changes that may occur in the crystal structure, and the behavior of the samples due to addition of metal dopants. The dosimetric characteristics of the products were determined by applying TL technique. Thermoluminescence studies showed two glow peaks of Pr, Ho, and Nd along with Cu-added samples, one of them is always at around 90 °C and the second TL peak around 180, 275, and 285 °C, respectively. Therefore, this study showed that these materials are promising thermoluminescent material for dosimetric applications.

Rare earth borates investigations were divided into two parts. In the first part, the effect of microwave energy on particle size and structure of some LnBO_3 (where $\text{Ln}=\text{La, Nd, Dy, Ho}$) compounds were investigated. Urea and sucrose were used as a microwave active organic additive.

In the second part of the borates, since there are still uncertainties about the crystal structure of optically important rare earth orthoborates our aim is to investigate the structure of all pure lanthanide borate compounds ($\text{Ln}=\text{Y, La-Lu}$). For this purpose, the synthesized powder were subjected to Rietveld structural analysis by using GSAS software.

1.6. Outline of The Thesis

Chapter 1 reveals a detailed literature survey covering general information, uses and reserves of borates, phosphates, definition of TL property and Rietveld refinement.

Chapter 2 deals with the materials used for the synthesis of the borates, and phosphates, the analytical method applied and the experimental procedures implemented throughout the thesis.

In Chapter 3, the experimental results of lanthanide oxide phosphates, pyrophosphates and orthoborates are presented and discussed in detail, based on explanations and comparisons of XRD, FTIR, Raman, SEM, TL and Rietveld analysis studies outputs.

Finally in Chapter 4, the main points that can be drawn from this thesis are emphasized.

CHAPTER 2

EXPERIMENTAL

2.1. Chemicals and Experimental Procedure

2.1.1. Sodium Lanthanide Oxide Phosphates ($\text{Na}_2\text{LnOPO}_4$)

The following solid powders were used in the solid state reactions of various rare earth oxides: La_2O_3 , Nd_2O_3 , Sm_2O_3 , Gd_2O_3 , Dy_2O_3 , Ho_2O_3 , Er_2O_3 , Yb_2O_3 , Na_2CO_3 , and $\text{NH}_4\text{H}_2\text{PO}_4$. They are commercial reagents used without further purification and supplied from the Merck, Fluka, Aldrich, and Sigma.

All preparations were made by spontaneous crystallization with stoichiometric proportions of reactants in oxygen atmosphere with the following formula:

Desired quantities of salts and oxides were weighed separately and crushed well in agate mortar for homogenization. Then the mixture was transferred into a porcelain crucibles and put into a furnace for heating. The mixtures were heated at 500 °C for 11 hours, 700 °C for 10 hours, 800 °C for 5 hours, 850 °C for 5 hours, 900 °C for 15 hours, 950 °C for 25 hours, 1100 °C for 15 hours. The products were taken from the furnaces directly to outside. All the samples were kept in desiccators against moisture. The starting materials weights are all 1.0000 g for lanthanide oxides. The weight losses of the products are in good agreement with the theoretical ones. The products were subjected to X-ray diffraction and IR analysis after each sintering process.

2.1.2. Strontium Pyrophosphates

2.1.2.1. Solid solutions of $\text{Sr}_2\text{P}_2\text{O}_7$ and ZrP_2O_7

The ZrO_2 , SrCO_3 , and $\text{NH}_4\text{H}_2\text{PO}_4$ (from Merck, Aldrich and Allied Chem.) powders were used in the solid state reactions.

The experiments were divided into two sets. All preparations were made in air with the aid of muffle furnaces. Stoichiometric amounts of reactants and heat treatment details of both sets are given in Table 2.1a and 2.1b. Desired quantities of initial reactants were weighed separately and crushed well in agate mortar. Then the mixture was transferred into a porcelain crucible and put into a furnace for heating. The products were subjected to X-ray powder diffraction and IR analysis after each sintering process. All the samples were kept in desiccators against moisture.

Table 2.1. Composition, and heating treatment of $\text{Sr}_2\text{P}_2\text{O}_7$ added ZrP_2O_7 and ZrP_2O_7 added $\text{Sr}_2\text{P}_2\text{O}_7$.

Table 2.1a. Composition, and heat treatment conditions of $\text{Sr}_2\text{P}_2\text{O}_7$ added ZrP_2O_7 .

Composition	900 °C
ZrP_2O_7	14.5h
ZrP_2O_7 :10 % $\text{Sr}_2\text{P}_2\text{O}_7$	10.5h
ZrP_2O_7 : 5 % $\text{Sr}_2\text{P}_2\text{O}_7$	10.5h
ZrP_2O_7 : 1 % $\text{Sr}_2\text{P}_2\text{O}_7$	10.5h
ZrP_2O_7 : 0.5 % $\text{Sr}_2\text{P}_2\text{O}_7$	10.5h
ZrP_2O_7 : 0.1 % $\text{Sr}_2\text{P}_2\text{O}_7$	10.5h
ZrP_2O_7 : 0.05 % $\text{Sr}_2\text{P}_2\text{O}_7$	10.5h
ZrP_2O_7 : 0.03 % $\text{Sr}_2\text{P}_2\text{O}_7$	10.5h

Table 2.1. Continued.

Table 2.1b. Composition, and heat treatment conditions of ZrP_2O_7 added $\text{Sr}_2\text{P}_2\text{O}_7$.

Composition	900 °C
$\text{Sr}_2\text{P}_2\text{O}_7$	14.5h
$\text{Sr}_2\text{P}_2\text{O}_7$: 10% ZrP_2O_7	10.5h
$\text{Sr}_2\text{P}_2\text{O}_7$: 5% ZrP_2O_7	10.5h
$\text{Sr}_2\text{P}_2\text{O}_7$: 1% ZrP_2O_7	10.5h
$\text{Sr}_2\text{P}_2\text{O}_7$: 0.5 % ZrP_2O_7	10.5h
$\text{Sr}_2\text{P}_2\text{O}_7$: 0.25 % ZrP_2O_7	10.5h
$\text{Sr}_2\text{P}_2\text{O}_7$: 0.1 % ZrP_2O_7	10.5h
$\text{Sr}_2\text{P}_2\text{O}_7$: 0.05 % ZrP_2O_7	10.5h

2.1.2.2. Thermoluminescence properties of Copper and Rare Earth Elements added $\text{Sr}_2\text{P}_2\text{O}_7$

The addition was done by mixing previously produced (Section 2.1.2.1.) pure $\text{Sr}_2\text{P}_2\text{O}_7$ with %5 CuO and % 0.5, 1, 2, 3, 4, 5, 10, 15 (by weight) rare earth oxides (Y_2O_3 , La_2O_3 , CeO_2 , Pr_6O_{11} , Nd_2O_3 , Sm_2O_3 , Eu_2O_3 , Gd_2O_3 , Tb_2O_3 , Dy_2O_3 , Ho_2O_3 , Er_2O_3 , Tm_2O_3 , Yb_2O_3 , Lu_2O_3).

The mixtures were grounded in an agate mortar. They, then, were transferred in alumina ceramic crucibles and heated at 950 °C for 10 hours in muffle furnaces. All preparations were made by spontaneous crystallization in air atmosphere. All the samples were kept in desiccators against moisture.

2.1.3. Rare Earth Orthoborates

In this part of the thesis, rare earth orthoborates were synthesized by using microwave-assisted and solid state synthesis methods.

2.1.3.1. Microwave-Assisted Synthesis of LnBO₃ (where Ln=La, Nd, Dy, Ho)

In the present work, we prepared LnBO₃ (Ln=La, Nd, Dy, Ho) powder samples by using either urea or sucrose in less energetic microwave-assisted reaction method at 1000 W starting with Ln₂O₃ (where Ln=La, Nd, Dy, Ho) and H₃BO₃ (ratio=1:2) and further two hour heating was applied at 950 °C after this process in muffle furnace as shown in Table 2.2.

Microwave processing of materials differs fundamentally from conventional processing in terms of its heat mechanism. In a microwave oven, heat is generated within the sample itself by the interaction of microwaves with the material.

Table 2.2. The composition and heat treatment conditions of orthoborate mixtures prepared by microwave-assisted synthesis.

Composition Re ₂ O ₃ +2H ₃ BO ₃	%40 Urea or Sucrose By Weight	MW treatment (Watt-Minutes)	Heat Treatment (°C-Hours)
La ₂ O ₃ + 2H ₃ BO ₃	%40 Urea	1000W-10 Min.	950 °C-2 Hours
Nd ₂ O ₃ + 2H ₃ BO ₃	%40 Urea	1000W-10 Min.	950 °C-2 Hours
Dy ₂ O ₃ + 2H ₃ BO ₃	%40 Urea	1000W-10 Min.	950 °C-2 Hours
Ho ₂ O ₃ + 2H ₃ BO ₃	%40 Urea	1000W-10 Min.	950 °C-2 Hours

Nd ₂ O ₃ + 2H ₃ BO ₃	%40 Sucrose	1000W-10 Min.	950 °C-2 Hours
Dy ₂ O ₃ + 2H ₃ BO ₃	%40 Sucrose	1000W-10 Min.	950 °C-2 Hours
Ho ₂ O ₃ + 2H ₃ BO ₃	%40 Sucrose	1000W-10 Min.	950 °C-2 Hours

2.1.3.2. Solid State Synthesis of LnBO₃ (where Ln= Y, La, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu)

Starting materials for the preparation of mixtures consisted of reagent grade boric acid, H₃BO₃, powder and thirteen high-purity lanthanide oxides [Ln₂O₃ (where Ln= Y, La, Nd, Sm, Eu, Gd, Dy, Ho, Er, Tm, Yb, Lu) and Tb₄O₇] obtained commercially. The purity of oxides was better than 99.9%.

The mixtures [Ln₂O₃:H₃BO₃=2:1 and Tb₄O₇:H₃BO₃=1/28] were grinded, heated in an Al crucible at 300 °C for 5 hours, 500 °C for 5 hours, 700 °C for 5 hours, 900 °C for 10 hours, 1000 °C for 5 hours in air atmosphere with intermediate grindings. The compounds were finally quenched to room temperature in air. All the samples were kept in desiccators against moisture.

2.2. Instrumentation

2.2.1. XRD-X-Ray Diffraction

To study the crystal structure of the produced new phases from the solid state reactions, X-ray Diffraction (XRD) investigations were carried out.

Specific d value for each peak was calculated from the corresponding 2θ values by using the Bragg's law given in Equation 2.1.

$$n\lambda = 2d\sin\theta \quad (2.1)$$

where,

n: an integer showing order in crystal planes (n=1, 2, 3 .., n)

λ: the wavelength (λ=1.54056 Å for Cu anode)

d: the distance between successive parallel planes, Å

2θ: the angle between incidence and diffraction of the X-ray beam from the given lattice plane.

The identification was done by comparing those d values with the characteristic d values in the International Centre for Diffraction Data (ICDD) and Inorganic Crystal Structure Database (ICSD) cards of appropriate materials.

In X-ray crystallography, the angstrom (Å) unit has always been the preferred measure of wavelength. Even though the latest recommendation from the International Union of Pure and Applied Chemistry (IUPAC) discourages use of the angstrom and encourages use of the nanometer (nm; 1×10^{-9} m), the powder diffraction community has fought for retention of the angstrom and this remains the common unit in the use in the field today (Jenkins and Snyder, 1996). For this reason, in this thesis we will use the angstrom unit.

2.2.1.1. Rigaku Diffractometer

The structural analysis of samples was checked by X-ray Powder Diffraction. The XRD data were collected using Rigaku X-ray Diffractometer (Model, Miniflex) with CuK_α (30 kV, 15 mA, $\lambda=1.54051$ Å) radiation at room temperature at Chemistry Department of Middle East Technical University. Scanning was performed between 5-145 degree 2 Theta, generally. The measurements were made with 0.01 and 0.05 degree steps and 1 degree/minute rate. The divergence slit was variable and scattering and receiving slit were 4.2 degree and 0.3 mm, respectively. Rigaku Miniflex diffractometer with nickel-filtered CuK_α radiation (15mA, 30kV). This device was used only for preliminary investigation and the X-ray data never used in the Rietveld refinements.

2.2.1.2. Panalytical Diffractometer

For rietveld analysis of lanthanide orthoborate powders, more accurate intensities were then collected on a X'PERT PRO X-ray vertical diffractometer (Bragg-Brentano parafocusing geometry) of PANalytical X-ray systems equipped with ultrafast solid state detector PIXCEL using CuK_α radiation (45 kV, 40 mA, $\lambda=1.5406$ Å) between 10° to 150° with 0.026 sampling rate in continuous mode. The X-ray beam contained $\text{CuK}_{\alpha 1}$ and $\text{CuK}_{\alpha 2}$ wavelengths, respectively with $\lambda_{\text{K}_{\alpha 1}}=1.5406$ Å and $\lambda_{\text{K}_{\alpha 2}}= 1.5444$ Å and intensity ratio $\text{CuK}_{\alpha 2}/\text{CuK}_{\alpha 1}$ of 0.5.

2.2.1.3. Stoe Stadi-P Diffractometer

In order to investigate the differences in powder patterns between dual CuK α radiation and monochromatic CoK α_1 , some of rare earth borates were scanned by STOE STADI-P CoK α_1 ($\lambda=1.78896 \text{ \AA}$) with Ge(111) monochromator.

2.2.2. FTIR

The vibrational modes of molecules in the samples were defined by the help of Nicolet 400 and 510 FTIR Infrared Spectrometer in the region 400-2000 cm^{-1} . Spectroscopic grade KBr was used for making IR pellets. KBr was dried at 180 $^{\circ}\text{C}$ for about 1 day before using. The ratio of KBr to sample was 100 mg:3 mg.

In KBr pellet method, the solid samples is finely pulverized with pure, dry KBr for spectroscopy. The mixture is pressed in a hydraulic press to form a transparent pellet, and the spectrum of the pellet is measured. It is important that the solids be extremely finely divided and well mixed. The pellet is pressed in a special dye that can be evacuated in order to avoid entrapped air, which causes cloudiness in the pellet.

2.2.3. Raman

Jobin Yvon-Horiba was used for Raman scattering spectra. This instrument has He-Ne laser wavelength of 632.83 nm and Peltier cooled CCD detector. Laser power was 10 mWatt, and detector worked at -75 $^{\circ}\text{C}$. The slit width was 200 μm , and grating with 600 blazes/cm was used. Data accumulation duration was 60 second, and each accumulation was done for 5 times.

2.2.4. SEM-EDS

The surface characterization of powder specimens were performed by Scanning Electron Microscopy (SEM) technique. Scanning Electron Micrographs were taken by JEOL JSM 6400 (20 kV), equipped with NORAN system 6 X-ray Microanalysis System & Semafore Digitizer at Metallurgical and Materials Engineering Department of Middle East Technical University. The microscope is equipped with secondary and backscattered electron detectors and X-ray microanalysis system, and is capable of providing both topographical and compositional information about the specimen.

Samples were coated with a very thin layer of gold-palladium (Au-Pd) alloy by using HUMMLE VII Sputter Coating Device (ANATECH). The morphology of the samples was investigated by taking microphotographs of SEM images from different parts of the sample surfaces.

2.2.5. Thermoluminescence

In order to investigate the dosimetric properties and to present the thermoluminescence characteristics of the samples were taken by means of TL glow curves. Thermoluminescence glow curves of copper and rare earth added $\text{Sr}_2\text{P}_2\text{O}_7$ compounds were obtained by using a Harshaw QS 3500 Manual type TL reader which has an S-11 response photomultiplier tube at Physics Engineering Department of Gaziantep University. The reader is interfaced to a PC where the TL signals were studied and analyzed. Glow curves were measured using a platinum planchet at a linear heating rate of $1\text{ }^\circ\text{C s}^{-1}$ from room temperature up to $400\text{ }^\circ\text{C}$.

A standard clean glass filter was always installed in the reader between sample and photomultiplier tube. This filter allows the light whose wavelength is between ≈ 250 and ≈ 1000 nm to pass through it and thereby eliminates unwanted infrared light emitted from the heater.

All samples were irradiated for 5 minutes at room temperature with a ^{90}Sr – ^{90}Y beta (β) source delivering about 0.9 Gy/min. 15 milligrams of powder were used for each measurement. The time duration between irradiation and TL reading was always kept constant at about 1 min to eliminate the possible fading in the low temperature peak between room temperature and 150 °C.

All experiments were performed inside a dark room in order to avoid any influence of the environment light on the glow curves.

2.3. Heat Treatment Furnaces

Heat treatment experiment were executed by using Protherm, PLF 125 Model furnace in air atmosphere. To avoid melting, reactions started at room temperature.

2.4. Crystallographic Data Analysis Programs

Although, we always tried to find best conditions for scanning diffractograms in different diffractometers, we have faced difficulties obtaining good peak profiles, background functions, smoothing, peak search, etc. because of the sample characteristics under investigation. In order to correct instrumental broadening and proceed the Rietveld refinement, we used CELREF and GSAS, respectively.

2.4.1. CELREF

CELREF (Altermatt and Brown, 1987), developed at Laboratoire des Matériaux et du Génie Physique Ecole Nationale Supérieure de Physique de Grenoble (INPG) Domaine Universitaire BP 46, 38402 Saint Martin d'Hères France, can refine the unit cell parameters of given compounds whose unit cell parameters and space group previously indexed or solved.

2.4.2. GSAS-General Structure Analysis System

GSAS is a set of programs for the processing and analysis of both single crystal and powder diffraction data obtained with X-rays or neutrons. It is capable of handling all of these types of data simultaneously for a given structural problem. In addition, it can handle powder diffraction data from a mixture of phases refining structural parameters for each phase. EXPGUI is graphical user interface program of GSAS for refinements. (Larson A.C. and Von Dreele, 2000, Toby, 2001).

CHAPTER 3

RESULTS AND DISCUSSION

3.1. Synthesis of Sodium Lanthanide Oxide Phosphates $\text{Na}_2\text{LnOPO}_4$ (Ln= La, Nd, Sm, Gd, Dy, Ho, Er, Yb)

The following powders were heated in the solid state reactions of various rare earth oxides: La_2O_3 , Nd_2O_3 , Sm_2O_3 , Gd_2O_3 , Dy_2O_3 , Ho_2O_3 , Er_2O_3 , Yb_2O_3 , Na_2CO_3 , and $\text{NH}_4\text{H}_2\text{PO}_4$ at 500 °C for 11 hours, 700 °C for 10 hours, 800 °C for 5 hours, 850 °C for 5 hours, 900 °C for 15 hours, 950 °C for 25 hours, 1100 °C for 15 hours.

Parallel to these experiments, we have tried several experiments to synthesize KTP-like single crystals of $\text{Na}_2\text{LnOPO}_4$ by using several chemicals for flux reactions. Unfortunately, our all experiments to obtain single crystal products were failed and it is not possible to find structural data about the related compounds in the literature to perform Rietveld analysis for structural solution.

After the final heating at 1100 °C, X-ray diffraction patterns of products were obtained and the final orthorhombic compounds are sectioned into two sets. In the X-ray diffraction pattern of the first set (Figure 3.1), $\text{Na}_2\text{LaOPO}_4$, $\text{Na}_2\text{NdOPO}_4$, $\text{Na}_2\text{SmOPO}_4$ products are differentiated according to their splitting peak as presented by Kizilyalli (Gönen et al. 2000). The second set, $\text{Na}_2\text{GdOPO}_4$, $\text{Na}_2\text{DyOPO}_4$, $\text{Na}_2\text{HoOPO}_4$, $\text{Na}_2\text{ErOPO}_4$, and $\text{Na}_2\text{YbOPO}_4$, was also indexed in orthorhombic system without having splitting peak.

3.1.1. Results of X-ray Diffraction Investigations

In the synthesis steps of both sets, as the reaction proceeded at 950 °C for 25 hours, solid state reactions at these stages also did not reveal the expected products and the XRD patterns of the products showed a great similarity with each other but they are not desired ones. The IR spectra of the products obtained at these steps have supported this idea. Therefore, in order to obtain products the temperature was increased. Prolonged heating of the products at 1100 °C (three 5 hours periods and grinding in between) resulted in single phase product which is orthorhombic $\text{Na}_2\text{LnOPO}_4$ (where Ln= La, Nd, and Sm). The XRD patterns of set 1 are presented in Figure 3.1.

It is known from the previous work of (Gönen et al. 2000) that $\text{Na}_2\text{LaOPO}_4$ has orthorhombic structure with the refined unit cell parameters of $a= 13.657(5)$, $b=11.076(5)$, and $c=6.7295(3)$ Å. In this study, the diffraction peaks of our $\text{Na}_2\text{LaOPO}_4$ can be indexed on the basis of orthorhombic cell with the refined unit cell parameters of $a= 13.60(1)$, $b=12.71(1)$, $c=6.96(1)$ Å using CELREF program (Altermatt and Brown, 1987) and the space group $Pmm2$. Table B.1 shows the X-ray diffraction data of our new $\text{Na}_2\text{LaOPO}_4$. The unit cell parameters of previously synthesized sodium lanthanum oxide phosphate and those from new phase show similarities with small differences. The reason of this situation is that former one was containing $\text{Na}_3\text{La}(\text{PO}_4)_2$ together with $\text{Na}_2\text{LaOPO}_4$. Another reason for the differences is the production temperature. The former one was obtained at 1000 °C while our final product $\text{Na}_2\text{LaOPO}_4$ was produced at 1100 °C.

The unit cell parameters of other two products in set 1, $\text{Na}_2\text{NdOPO}_4$, and $\text{Na}_2\text{SmOPO}_4$, were also indexed in orthorhombic system with the space group $Pmm2$. X-ray diffraction data and hkl values of $\text{Na}_2\text{LaOPO}_4$, $\text{Na}_2\text{NdOPO}_4$, and $\text{Na}_2\text{SmOPO}_4$ are given in Table B.1, B.2, B.3, respectively.

Figure 3.1. X-Ray Diffraction Patterns of $\text{Na}_2\text{LaOPO}_4$, $\text{Na}_2\text{NdOPO}_4$, $\text{Na}_2\text{SmOPO}_4$.

The calculated hkl values and the XRD data of set 1, where samples prepared under the highest temperature 1100 °C, was in accordance with Gönen's work (Gönen et al. 2000). Table 3.1 summarized the relation between unit cell dimensions of set 1.

Table 3.1. The unit cell parameters of Na₂LaOPO₄, Na₂NdOPO₄, Na₂SmOPO₄.

	Na ₂ LaOPO ₄	Na ₂ NdOPO ₄	Na ₂ SmOPO ₄
a (Å)	13.60(1)	13.466(5)	13.54(1)
b(Å)	12.71(1)	12.547(6)	12.577(8)
c(Å)	6.96(1)	6.932(5)	7.047(5)

The most intense peaks were observed at d=2.8687, 2.8598, and 2.8732 Å for Na₂LaOPO₄, Na₂NdOPO₄, and Na₂SmOPO₄, respectively. Furthermore, the splitting of peaks were observed at d=3.35 and 3.30 Å, d=3.29 and 3.25 Å, d=3.29 and 3.25 Å, respectively while this splitting observed at 3.27 and 3.23 Å in the XRD data of lanthanum compound (Gönen et al. 2000).

In the second set, Na₂DyOPO₄, Na₂HoOPO₄, Na₂ErOPO₄, and Na₂YbOPO₄ were synthesized for the first time in this study at 1100 °C and results were given in Seyyidoglu et al. (2008). A new phase of Na₂GdOPO₄ was also obtained by using solid state reaction at the same temperature. The X-ray diffraction patterns of this set were given in Figure 3.2. The indexing of the data showed that Na₂GdOPO₄ and the new products Na₂DyOPO₄, Na₂HoOPO₄, Na₂ErOPO₄, and Na₂YbOPO₄, are also orthorhombic and the space group of this set is also Pmm2. The hkl indices and d observed values are given in Table B.4, B.5, B.6, B.7, and B.8 for Na₂GdOPO₄, Na₂DyOPO₄, Na₂HoOPO₄, Na₂ErOPO₄, and Na₂YbOPO₄, respectively. Table 3.2. represents the unit cell parameters of the second set where there are similarities. Similar hkl values observed in all products and there are some resemblances between these products and the first set, Na₂LnOPO₄ (Ln= La, Nd, and Sm). The splitting of the peak around d=3.45 and 3.25 Å was not observed in these second set products.

Figure 3.2. X-Ray Diffraction Patterns of $\text{Na}_2\text{GdOPO}_4$, $\text{Na}_2\text{DyOPO}_4$, $\text{Na}_2\text{HoOPO}_4$, $\text{Na}_2\text{ErOPO}_4$, $\text{Na}_2\text{YbOPO}_4$.

Table 3.2. The unit cell parameters of Na₂GdOPO₄, Na₂DyOPO₄, Na₂HoOPO₄, Na₂ErOPO₄, Na₂YbOPO₄.

	Na ₂ GdOPO ₄	Na ₂ DyOPO ₄	Na ₂ HoOPO ₄	Na ₂ ErOPO ₄	Na ₂ YbOPO ₄
a(Å)	13.37(1)	13.66(2)	13.148(4)	13.563(5)	13.501(7)
b(Å)	12.775(9)	12.609(9)	12.577(2)	12.604(4)	17.579(9)
c(Å)	6.910(9)	6.611(6)	6.967(1)	7.003(3)	6.729(4)

3.1.2. Results of FTIR and Raman Investigations

According to Uztetik-Amour et al. (1995), ν_{as} and ν_s bands are assigned as ν_3 (F₂), observed between 1136, 1099, 1034, 982, 965, and 945 cm⁻¹. Table 3.3 and 3.4. indicate the IR and Raman data and assignments of the first and second sets, respectively. In the IR tables of our results, ν_3 (F₂) bands are between 1084-1099, 1030-1053, 976-982, 957-971, and 945-954 cm⁻¹ for both sets, respectively. Uztetik-Amour and Kizilyalli (1995) also indicated that bands at 926, and 909 cm⁻¹ are due to stretching modes, assigned as ν_1 (A₁) and present in our samples in between 921-926 and 913 cm⁻¹. They also stated that the bands around 604, 579, 560, 548, 523, and 470 cm⁻¹ are ascribed to the δ (O-P-O) which is assigned as ν_4 (F₂). These bands present in between 598-605, 574-579, 559-565, 541- 551, 523-526, 468-472, and 403-409 cm⁻¹ for both sets, respectively. Finally, bands at 406, 381, and 367 cm⁻¹ are attributed to deformation modes and assigned as ν_3 (E) given by Uztetik-Amour and Kizilyalli (1995). In the IR tables of the both sets, the bands around 403-409 cm⁻¹ are obvious. Some of these bands were observed in Raman spectra of the products.

The presence of the tetrahedral PO₄ ion is obvious since the tetrahedral symmetry has four internal modes of vibration, $\nu_1=938$ cm⁻¹ (R), $\nu_2=420$ cm⁻¹ (R), $\nu_3=1017$ cm⁻¹ (IR, R), and $\nu_4= 567$ cm⁻¹ (IR, R) (Uztetik-Amour and Kizilyalli 1995). They also mentioned that the antisymmetric stretching modes are found between 1290 and 1050 cm⁻¹ and the symmetric modes between 1050 and 900 cm⁻¹. In our results these bands also present.

Husson et al. (1988) and Nakamoto (1971) have reported that the highest frequency observed is due to antisymmetric stretching involving the terminal bond, a bond between a phosphorus atom and a so-called unshared oxygen atom or the shortest bond. For instance in KTiOPO_4 compound, $\nu_{\text{as}}\text{P-O}$ was observed at around 1135 cm^{-1} . The stretching modes are 926 and 909 cm^{-1} and these bands were observed in both sets in between 921 - 926 and 913 cm^{-1} (Uztetik-Amour and Kizilyalli 1995).

The bands between 604 and 470 cm^{-1} are fundamental bands for $\delta(\text{O-P-O})$ which are 605 and 478 cm^{-1} in this thesis. Finally, our samples have deformation modes which are between 406 and 367 cm^{-1} . The products have bands around 403 - 409 cm^{-1} and since FTIR instrument can detect peaks to 400 cm^{-1} , the other deformation peaks are not present in this study. These results confirmed that our products have KTP related $\text{Na}_2\text{GdOPO}_4$ structure.

Table 3.3. IR band locations for a) Na₂LaOPO₄, Na₂NdOPO₄, Na₂SmOPO₄, and b) Na₂GdOPO₄, Na₂DyOPO₄, Na₂HoOPO₄, Na₂ErOPO₄, Na₂YbOPO₄ (cm⁻¹).

3.1.3. Results of Scanning Electron Microscopy Investigations

The particle size and the morphology of both set of specimens were investigated by using SEM as given in Figure 3.3. These SEM observations showed that some uniformity exists between the specimens of both sets in their shape and particle size. Among these products, particle size can be given as in between 1-10 μm .

3.2. SYNTHESIS OF $\text{Sr}_2\text{P}_2\text{O}_7$ - ZrP_2O_7 SOLID SOLUTION AND SYNTHESIS OF CuO AND RARE EARTH OXIDES ADDED TO $\text{Sr}_2\text{P}_2\text{O}_7$

3.2.1. SYNTHESIS OF $\text{Sr}_2\text{P}_2\text{O}_7$ - ZrP_2O_7 SOLID SOLUTION

ZrP_2O_7 , zirconium pyrophosphate, was synthesized at 900 °C by solid state reaction of ZrO_2 and $\text{NH}_4\text{H}_2\text{PO}_4$ and X-ray diffraction studies indicated that the product was composed of a single phase. The XRD data can be easily indexed into the cubic system with $a=8.248(6)$ Å shown in Table B.9. and the space group is Pa-3. This data is very close to the ICDD Card No: 24-1491 where $a=8.245$ Å. Khosrovani et al. (1996) solved the structure of cubic ZrP_2O_7 at room temperature and refined by using a combination of modeling and high-resolution neutron powder diffraction data. The cell edge is given as 24.74 Å and the space group is Pa-3. They proposed that the superstructure present at room temperature disappears at about 290 °C. Withers et al. (2001) mentioned that the unmodulated parent structure of zirconium pyrophosphate made up of corner-connected ZrO_6 octahedra and PO_4 tetrahedra. They (Withers et al. 2001) also explained that above 294 °C, the parent cell parameter is multiplied by 3 to enable direct comparison with the low-temperature superstructure phase. Therefore, our unit cell and space group data are in agreement with these studies (Khosrovani et al. 1996 and Withers et al. 2001).

3.2.1.1. Results of X-ray Diffraction Investigations

XRD patterns of pure and (10, 5, 1, 0.5, 0.1, 0.05, 0.03) % $\text{Sr}_2\text{P}_2\text{O}_7$ added ZrP_2O_7 are given in Figure 3.4. The unit cell parameters of the set 1 has very little change in between 8.248(6)-8.233(8) Å. According to these results it can be concluded that, in this solid solution, orthorhombic addition didn't alter the cubic structure so much. The cell edge length decreased to 8.233(8) from 8.248(6) Å.

The pure $\text{Sr}_2\text{P}_2\text{O}_7$ was synthesized at the same experimental conditions and indexed with respect to ICDD Card No: 24-1011. This X-ray data, which are given in Table B.10., were indexed in the orthorhombic system, and the refined lattice constants were found to be $a=8.900(2)$, $b=13.151(2)$, and $c=5.402(2)$ Å by using CELREF refinement program (Altermatt et al. 1987).

Figure 3.4. X-ray Diffraction Patterns of a) Pure and b)10, c)5, d)1, e)0.5, f)0.1, g)0.05, h)0.03 % $\text{Sr}_2\text{P}_2\text{O}_7$ added ZrP_2O_7 .

In Figure 3.5., XRD patterns of pure and (10, 5, 1, 0.5, 0.25, 0.1, 0.05) % ZrP_2O_7 added $\text{Sr}_2\text{P}_2\text{O}_7$ were given. Same trends were observed for three unit cells. They slightly change in between $a=8.909(5)$ - $8.877(5)$, $b=13.163(3)$ - $13.12(1)$, and $c=5.403(2)$ - $5.386(4)$ Å. Since small fluctuations were observed, it can be concluded that cubic ZrP_2O_7 couldn't enter and destroy the orthorhombic $\text{Sr}_2\text{P}_2\text{O}_7$ structure.

Figure 3.5. X-ray Diffraction Patterns of a) Pure and b) 10, c) 5, d) 1, e) 0.5, f) 0.25, g) 0.1, h) 0.05 % ZrP_2O_7 added $\text{Sr}_2\text{P}_2\text{O}_7$.

3.2.1.2. Results of the Infrared and Raman Investigations

In addition to XRD studies, we measured infrared and Raman spectra of the synthesized products in order to confirm the functional groups in all products. The band positions of the Infrared and Raman spectra of the set 1 is given in Table 3.5 and 3.6, respectively and Table 3.7. and Table 3.8. is the band positions of the infrared and Raman spectra for set 2 obtained in this research. Examination of these tables shows that there are some coincidences in the infrared and Raman spectra.

The assignment of the $P_2O_7^{4-}$ modes is carried out in terms of PO_3 and P-O-P vibration [Pillai et al. (1999), Baran et al. (2004)]. The symmetric and antisymmetric stretching frequencies of PO_3 in $P_2O_7^{4-}$ are observed in the region $1157-1002\text{ cm}^{-1}$. For POP, symmetric modes were observed in the region $779-736\text{ cm}^{-1}$. Guler et al. (2005) and coworkers observed the bands due to δOPO , δPO_3 , δPOP deformations in the region $595-464\text{ cm}^{-1}$. In our studies, we observed these bands in the between $609-455\text{ cm}^{-1}$. Khay et al. (2001a, 2001b) mentioned that the deformation bands are between 630 and 373 cm^{-1} and our peaks around these frequencies are consistent with the literature values. They also reported that all bands located below are external vibrational modes. So, the bands below 334 cm^{-1} are external vibrational modes.

Khorosvani et al. (1996) observed unusual P-O-P bond angle in ZrP_2O_7 . In their work, the $3 \times 3 \times 3$ superstructure present at room temperature disappears at about $290\text{ }^\circ\text{C}$, and all P-O-P angles of P_2O_7 are then constrained by symmetry to be $180\text{ }^\circ\text{C}$ on average. In the same reference, they also mentioned that the angle for P-O-P linkages is normally in the range $130-160^\circ$ and the P-O-P bond angle of 180° is unfavorable, and one expects that a structure containing such a linkage could only be stabilized at high temperature. We expected to have nonlinear POP bond for synthesized strontium pyrophosphate because they are cooled to room temperature after synthesis. Baran et al. (2004) indicated that for a linear bridge the symmetric mode should be only Raman active and the antisymmetric mode only IR active. The

appearance of both vibrations in both spectra is in an agreement with the presence of an angular bridge. We observed this situation in both the IR and Raman spectra.

The infrared and Raman bands observed are in agreement with the reported values for diphosphate compounds of tetravalent, mixed valent cations [Kızılyalı et al. (1993), Khay et al. (2001a, 2001a), Idrissi et al. (2004)] although their crystal systems are different.

3.2.1.3. Results of Scanning Electron Microscopy Investigations

The morphology of the products were investigated by taking SEM images. The SEM micrographs of pure ZrP_2O_7 and $\text{Sr}_2\text{P}_2\text{O}_7$ were given in Figure. D.1. In both figures, SEM images demonstrate the small particle size of these phosphates. In $\text{Sr}_2\text{P}_2\text{O}_7$ added ZrP_2O_7 samples, particles, before and after addition of $\text{Sr}_2\text{P}_2\text{O}_7$ to ZrP_2O_7 , are around $1\mu\text{m}$. Yet, SEM observations of ZrP_2O_7 added $\text{Sr}_2\text{P}_2\text{O}_7$ samples showed that one of the remarkable features of these products is that their sizes are larger than other set. In Figure D.2., EDX analysis of ZrP_2O_7 , 10% $\text{Sr}_2\text{P}_2\text{O}_7$ added ZrP_2O_7 , $\text{Sr}_2\text{P}_2\text{O}_7$, and 10% ZrP_2O_7 added $\text{Sr}_2\text{P}_2\text{O}_7$ are given. Sr addition was observed in all samples while the same trend was also investigated Zr added samples.

3.2.1.4. Results of Thermoluminescence Studies

The TL characteristics of pure and added strontium pyrophosphate have not been investigated in detail up to now. Natarajan et al. (2004) and his colleagues have recorded the TL glow curve of Eu-doped strontium pyrophosphate and they were reported two glow peaks at 465 and 565 K in the case of samples irradiated by ^{60}Co gamma rays up to 100 and 200 Gy. On the other hand, undoped $\text{Sr}_2\text{P}_2\text{O}_7$ sample did not show any TL (thermoluminescence) peak.

In the present study, all samples were firstly irradiated for 5 mins (≈ 4.5 Gy) at room temperature in the dark room by beta rays and then their glow curves were recorded. As seen in Figure 3.6., there is no change in the glow curve structure of all samples pure and 10, 5, 1, 0.5, 0.25, 0.1, 0.05 % ZrP_2O_7 added $\text{Sr}_2\text{P}_2\text{O}_7$ samples and their glow curves exhibit one strong glow peak at around 100°C with low intensity glow peaks at about 200 and 350°C . It is seen that the intensity of prominent glow peak at 100°C is continuously increased with decreasing concentration of ZrP_2O_7 and the maximum TL intensity was observed for the sample whose composition is $\text{Sr}_2\text{P}_2\text{O}_7$: 0.05% ZrP_2O_7 . Main peak temperature of all samples changes insignificantly by changing the concentration of ZrP_2O_7 .

Figure 3.6. Thermoluminescence Glow Curves of a) Pure and b) 10, c) 5, d) 1, e) 0.5, f) 0.25, g) 0.1, h) 0.05) % ZrP₂O₇ added Sr₂P₂O₇.

3.2.2. Synthesis of CuO and Rare Earth Added Sr₂P₂O₇

The structural analysis of pure strontium pyrophosphate was done in our previous work Seyyidoglu et al. (2007) and it was confirmed that the compound formed was α -Sr₂P₂O₇ in orthorhombic structure. In order to obtain good thermoluminescent phosphors, copper oxide and some rare earth oxides were added into Sr₂P₂O₇ host in this study. This work is a continuation of our systematic investigations of pyrophosphates with rare-earth elements. We report the results of these experiments on the synthesis and thermoluminescence properties of the compound, and the determination of their structure.

3.2.2.1. Results of X-ray Diffraction Investigations

Figure 3.7 - 3.12 shows that X-ray diffractions patterns of Pr₆O₁₁, Nd₂O₃ and Ho₂O₃ added with different amounts (0.5, 1, 2, 3, 4, 5, 10, 15%) into Sr₂P₂O₇. X-ray diffraction analysis demonstrated that the added rare earth metal oxides did not change patterns which were similar to orthorhombic Sr₂P₂O₇ means the structural stabilities of the compounds. As it can be seen from the Figure 3.7. (a), 15% and 10% Pr₆O₁₁ addition had small effects on the XRD patterns by lowering the intensities of two most intense peaks while remaining the peaks positions unchanged. As shown in the Figure 3.7. and 3.8., the 5% to 0.5% Pr₆O₁₁ added X-ray patterns were very similar to that of orthorhombic Sr₂P₂O₇. The X-ray pattern of Nd₂O₃ and Ho₂O₃ added polycrystalline powders showed a great similarity to the X-ray patterns of pure Sr₂P₂O₇. Similar XRD patterns were obtained for Nd₂O₃ and Ho₂O₃ addition shown in the Figure 3.9.-3.12.. It can be concluded that X-ray diffraction pattern for the added products in fair agreement with the pattern, indicating the phase purity of the as-synthesized samples of the title compound Sr₂P₂O₇.

3.2.2.2. Results of Thermoluminescence Studies

The TL characteristics of pure and rare earth oxides (Y_2O_3 , La_2O_3 , CeO_2 , Pr_6O_{11} , Nd_2O_3 , Sm_2O_3 , Eu_2O_3 , Gd_2O_3 , Tb_2O_3 , Dy_2O_3 , Ho_2O_3 , Er_2O_3 , Tm_2O_3 , Yb_2O_3 , Lu_2O_3) and CuO added strontium pyrophosphate have not been investigated until now (Seyyidoglu et al. 2007). It is well known that copper and rare earths are highly efficient elements to increase the TL intensity in many crystals. The attractive feature of lanthanides is their highly efficient narrow band f-f photoluminescence coming from trivalent lanthanide ions almost regardless of their environment: the luminescence was obtained in inorganic glass, sol-gel materials, polymers and in liquid crystals (Palewska et al. (2007)). The luminescence of lanthanide complexes originates from transitions between f-levels of central ions that are effectively shielded from the influence of external forces by filled 5s and 5p-shells (Palewska et al. (2007)). Therefore, CuO and some rare earth oxides added into host $\text{Sr}_2\text{P}_2\text{O}_7$ in order to obtain high TL intensity in this study. Figure 3.13 (a-f). shows some of the selected TL glow curves for samples prepared after different amounts of rare earth oxides addition. Based on the results presented in Figure 3.13 (a-f), it can be summarized that all $\text{Sr}_2\text{P}_2\text{O}_7$ products after addition have a TL peak around 90 °C as pure samples and another peaks above 150 °C in all samples at different temperatures and TL intensities (i.e, a glow peak at around 180 °C for Pr_6O_{11} , 275 °C for Nd_2O_3 , 285 °C for Ho_2O_3 , 225 °C for Er_2O_3 , and two glow peaks at around 185 and 305 °C for Tm_2O_3 and Dy_2O_3 added samples). These results show us that rare earths along CuO addition into $\text{Sr}_2\text{P}_2\text{O}_7$ increased the intensity of TL glow peaks above 150 °C of $\text{Sr}_2\text{P}_2\text{O}_7$. In particular, Pr_6O_{11} , Nd_2O_3 , Ho_2O_3 and Er_2O_3 added samples gave us the best TL results among them. Therefore, this study showed that these materials can be a promising thermoluminescent material for dosimetric applications since they have TL peaks over 100 °C and the intensity of the peaks is relatively higher.

3.3. SYNTHESIS OF LnBO_3 (where $\text{Ln}=\text{La, Nd, Dy, Ho}$) BY USING MICROWAVE-ASSISTED SOLID STATE REACTION

3.3.1. Microwave-Assisted Synthesis

The microwave-assisted synthesis is a rapidly developing area of research (Gomez et al. 2004, Wang et al. 2004, Dhage et al. 2002, Mirji et al. 2004). Microwave synthesis is generally quite faster, simpler, and very energy efficient. The exact nature of the interaction of microwaves with the reactants during the synthesis of ceramic materials is somehow unclear and speculative. However, energy transfer from microwaves to material is believed to occur either through resonance or by relaxation, both of which results in rapid heating.

In this part of the thesis, LnBO_3 ($\text{Ln}=\text{La, Nd, Dy, Ho}$) powder samples were prepared by using either urea or sucrose in less energetic microwave-assisted reaction method at 1000 W for 10 minutes starting with Ln_2O_3 (where $\text{Ln}=\text{La, Nd, Dy, Ho}$) and H_3BO_3 (ratio=1:2). Further two hours heating was applied at 950 °C after this process in muffle furnace to complete the reaction. The percentage of microwave active organic substances; urea and sucrose, were not chosen arbitrary. From zero percent to 100% (by weight) is tried for microwave experiments. Among these, below 40% samples did not activate the reaction and organic substances stayed unreacted which has no further effect in XRD patterns. The above 40%, organic microwave active reagent added samples did active in a very short time (in the first minutes) and this activation is so fast and uncontrollable. The mixtures of Ln_2O_3 (where $\text{Ln}=\text{La, Nd, Dy, Ho}$) and H_3BO_3 (ratio=1:2) without any microwave active organic substance addition did not activated by microwave and XRD investigations of these powders showed Ln_2O_3 and H_3BO_3 stayed unreacted and give only rare earth oxide peaks.

3.3.1.1. Results of X-ray Diffraction Investigations

In our case, the well mixed urea and sucrose were reacted during the microwave heating part of the experiments. This bubbling action of the additive microwave active organic additives happens generally in the last minute of ten minute microwave heating. The very viscous black samples were left to cool. Then, their XRD patterns were taken and given. As seen in Figure 3.14.b- Figure 3.23.b, after microwave heating part of the synthesis, patterns show pure Ln_2O_3 (where $\text{Ln}=\text{La, Nd, Dy, Ho}$) phase patterns.

However, because of the existence of residual unburned organic impurities as well as the uncompleted crystallization at lower temperatures, as prepared samples were subjected to solid state reaction to complete the reaction. The XRD patterns (Figure 3.14.c-3.21.c) taken after the two hours solid state reaction in muffle furnaces shows us that microwave-assisted synthesized LnBO_3 (where $\text{Ln}=\text{La, Nd, Dy, Ho}$) samples has same diffraction pattern with samples prepared by direct solid state reaction (Figure 3.14.a-3.21.a).

This is confirmed by the d-spacing values of the samples as shown in Table B.11.-B.14. In these tables, X-Ray Diffraction Data of LnBO_3 after a) Solid State Reaction, b) Microwave Heating With Urea and 2 hours Conventional Heating, c) Microwave Heating With Sucrose and 2 hours Conventional Heating were given. We have seen that while LaBO_3 and NdBO_3 samples prepared by both methods has same orthorhombic crystal structure with $Pnma$ (aragonite-type) space group as seen by d-spacing values in Table B.11-B.14., the DyBO_3 and HoBO_3 orthoborates has hexagonal crystal structure with space group of $P-6c2$ (vaterite-type). XRD data of LnBO_3 (where $\text{Ln}=\text{La, Nd, Dy, Ho}$) samples were subjected to CELREF (Altermat et al. 1987) program and unit cell parameters (given in Å) of were refined and summarized in Table 3.9.

MW-Sucrose + Solid State	a= 5.929(3)Å	a= 5.75(4)Å	a= 3.815(5)Å	a= 3.793(5)Å
	b= 8.334(6)Å	b= 8.109(7)Å		
	c= 5.122(4)Å	c= 5.059(4)Å	c= 8.911(2)Å	c= 8.851(2)Å

3.3.1.2. Results of Scanning Electron Microscopy Investigations

The results of XRD pattern of LnBO₃ samples (Figure 3.14.c.-3.21.c), indicates that FWHM of the samples after microwave activated solid state heating are larger than samples prepared by direct solid state reaction. These results showed the decrease in particle sizes of products. For this reason, products sent to Scanning Electron Microscope analysis to see the changes in morphology and particle sizes of microwave-assisted synthesized LnBO₃ samples.

In Figure D.3.-D.6., SEM images of LnBO₃ (where Ln=La, Nd, Dy, Ho) obtained by using a) Microwave-Assisted synthesis with urea, b) microwave-assisted synthesis with sucrose and c) solid-state reaction were given. In these figures, it is obviously seen that particles has submicron (<1µm) size and equally distributed for samples prepared by urea and sucrose. The particle sizes of direct solid solid state products are larger than 1µm and particles have not equal size and the distribution is random.

By using organic additives such as urea and sucrose, in the first part of the reaction, particles are equally distributed and probable mechanism is expected that during bubbling part of the organic substance activation in microwave-assisted part, these activators surrounded the other particles giving homogeneous distribution and while heating them at high temperatures these substances resist to agglomeration of residual powders. Most of the samples in Figure D.3.-D.6., has around 500 nm particle size in diameter.

3.4. RIETVELD REFINEMENT ANALYSIS OF LnBO₃ (where Ln= Y, La, Nd, Sm, Eu-Lu) STRUCTURES

Herein, in this final chapter of the thesis, we report the solid state reactions of Ln₂O₃ (where Ln= Y, La, Nd, Sm-Lu) and H₃BO₃ (ratio=1:2) performed at 900 °C for 10 hours and 1000 °C for 5 hours. The structure of the produced phases was identified by X-ray Diffraction studies. Then, their crystallographic studies were performed by using Rietveld refinement structural analysis. The Rietveld method is a full-pattern fit method. The measured profile and calculated profile are compared. By the variation of many parameters (background, profile, structural, zero shift, atomic positions, instrumental parameters, scale factor, unisotropic thermal parameters, etc.) the difference between the two profiles is minimized. After refining of these parameters, three dimensional structural analysis of the molecules can be drawn by, Diamond 2.1a.(Branderburg, 1996-1999) software packages were used.

3.4.1. Results of X-ray Diffraction Investigations

The X-ray diffraction patterns of the produced samples were collected by using Rigaku Miniflex Diffractometer and Panalytical X'Pert PRO Diffractometer.

3.4.1.1. Results of X-ray Diffraction Investigations of LnBO₃ scanned by using Rigaku Diffractometer

The X-ray Diffraction patterns of the EuBO₃ products scanned by Rigaku diffractometer were given in Figure 3.22. Based on the EuBO₃ XRD results, we deduced that the rise of the background level is due to absorption of the CuK α radiation and subsequent X-ray fluorescence. By using a K β filter subsequent X-ray fluorescence and the K β radiation can be avoided. The slight rise of the background was observed for the YBO₃, LaBO₃, YbBO₃, LuBO₃ and the strong rise of the bakground level for NdBO₃, SmBO₃, GdBO₃, TbBO₃, DyBO₃, HoBO₃, ErBO₃, TmBO₃ were observed.

Figure 3.22. X-Ray Diffraction Pattern of EuBO_3 Scanned by Using Rigaku Miniflex Diffractometer Between $5\text{-}145^\circ$ 2θ .

3.4.1.2. Results of X-ray Diffraction Investigations of LnBO₃ scanned by using Panalytical Diffractometer

Same samples were subjected to Cu radiation with K_β filter using Panalytical Diffractometer. For EuBO₃, the background level is seem normal in Figure 3.23. The slight increase of the background in the low angles resulted from the fixed divergence slit. Yet, it is normalized for the higher angles and we obtained nearly smooth background for whole sample. The same smooth background were observed for YBO₃, LaBO₃, NdBO₃, SmBO₃, GdBO₃, TbBO₃, DyBO₃, HoBO₃, ErBO₃, TmBO₃ YbBO₃, LuBO₃. Since our aim is to solve the crystal structure of rare earth orthoborates, high quality data were needed. All of these X-ray patterns has high quality data for Rietveld refinement with good FWHM values and with relatively much higher intensities with good peak shape.

X-ray Diffraction (XRD) patterns were analyzed by the X'Pert High Score Plus software version 2.2c (High Score Plus, 2007) with reference to the patterns of the International Centre for Diffraction Data database (Powder Diffraction File. PDF-2, 2002) as well as the Inorganic Crystal Structure Database (ICSD, 2005). According to these qualitative analysis by using search and match mode of the program, the following results firstly depicted from the library match (Table 3.10). The X-ray diffraction data of all lanthanide orthoborates were given in Table B.15.-B.27.

The LaBO₃ and NdBO₃ has correct space group as mentioned in ICSD cards. SmBO₃ has also triclinic crystal structure with *P-1* space group. For vaterite type of orthoborates (YBO₃, GdBO₃, TbBO₃, DyBO₃, HoBO₃, ErBO₃, TmBO₃ YbBO₃, LuBO₃) some of these cards are not fit well because of the structural differences in lanthanide orthoborates where all possible point groups has same d-spacings with different intensity values.

Yet, since atoms and atomic positions directly affects the intensity values of the given molecule, all possible space groups ($R3_2$, $P6_3/mmc$, $P6_3/m$, $C2/c$) were tried for vaterite type of orthoborates and the results of these trials is given in the Rietveld refinement results part. Among these crystal structures only $P6_3/mmc$ contains BO_3 groups in the structure while other ($R3_2$, $P6_3/m$, $C2/c$) has BO_4 groups in $B_3O_9^{9-}$ ring (Ren et al. 1999, Lin et al. 2004, Chadeyron et al. 1997b). This is proved by using IR spectroscopy in Chapter 3.4.2.

Table 3.10. Space groups, reference cards, unit cell parameters of lanthanide orthoborates.

LnBO₃	Space Groups (ICSD / ICDD Cards), Unit Cell Parameters
YBO₃	$P6_3/mmc$ (01-074-1929), a=3.778, c=8.814 Å
LaBO₃	$Pnma$ (00-012-0762), a=5.872, b=257, c=5.107 Å
NdBO₃	$Pnma$ (01-041-2407), a=5.7351, b=5.0564, c=8.0916 Å
SmBO₃	$P-1$ (01-040-0745), a=6.493, b=6.499, c=6.242 Å, $\alpha=107.79$, $\beta=107.42$, $\gamma=93.33^\circ$
EuBO₃	$P6_3/mmc$ (01-074-1931) + $P-1$ (01-088-0201) a=3.842, c=8.937 Å + a=6.468, b=6.477, c=6.22 Å, $\alpha=107.78$, $\beta=108.00$, $\gamma=92.07^\circ$
GdBO₃	$P6_3/mmc$ (01-074-1932), a=3.839, c=8.906 Å
TbBO₃	$P6_3/mmc$ (01-074-1933), a=3.793, c=8.847 Å
DyBO₃	$P6_3/mmc$ (01-074-1933), a=3.793, c=8.847 Å
HoBO₃	$P6_3/mmc$ (01-074-1934), a=3.784, c=8.836 Å
ErBO₃	$P6_3/mmc$ (01-074-1935), a=3.767, c=8.807 Å
TmBO₃	$P6_3/mmc$ (01-074-1936), a=3.753, c=8.789 Å
YbBO₃	$P6_3/mmc$ (01-074-1937), a=3.735, c=8.747 Å
LuBO₃	$P6_3/mmc$ (01-074-1938) + $R-3c$ (01-016-0525) a=3.727, c=8.722 Å + a=4.913, c=16.212 Å

Figure 3.23. X-Ray Diffraction Pattern of EuBO_3 Scanned by Using Panalytical Diffractometer with PIXCEL Detector Between $10\text{-}150^\circ$ 2θ .

3.4.2. Results of FTIR Investigations

IR spectroscopy was carried out with the objective of specifying and comparing the coordination of boron in LnBO₃ borates synthesized in this study. Aragonite type of orthoborates (LaBO₃ and NdBO₃) have vibration modes which can be described as follows: ν_3 (asymmetric stretching) in the region 1100 and 1400 cm⁻¹, ν_1 (symmetric stretching) near 940 cm⁻¹, ν_2 (out of plane bending) in the region 700-800 cm⁻¹, and ν_4 (in-plane bending) below 670 cm⁻¹ (Lemanceau et al. 1999). The close similarities in the IR spectra of LaBO₃ and NdBO₃ are evident as in Figure 3.24. and C.1, respectively. The ν_3 (asymmetric stretching) bands observed at 1277, 1246 and 1281, 1258 cm⁻¹, ν_1 (symmetric stretching) bands 947 and 966 cm⁻¹, ν_2 (out of plane bending) bands 819, 796, 718, and 788, 706 cm⁻¹, and ν_4 (in-plane bending) bands 609, 601, 539, 493 and 617, 594, 547 cm⁻¹ for LaBO₃ and NdBO₃, respectively. It will be noted that the behavior of ν_3 bands in the two structures serves as a distinguishing feature. For these compounds it is clear that boron atoms are in threefold coordination. The observed frequencies between 1350 and 1150 cm⁻¹ range correspond to the stretching frequencies of a coordinated BO₃ group (Lemanceau et al. 1999).

According to XRD results there is only one triclinic phase for SmBO₃ and two phases (triclinic and vaterite) for EuBO₃. Their FTIR spectra of these compounds were presented in Figure 3.25. and Figure C.2. The structure of these compounds consist of triclinic phases where the structure consist of BO₃³⁻ anions and Nd³⁺ and Eu³⁺ cations. The BO₃³⁻ anions are in the form of equilateral triangles with boron in the center. And the bands over 1150 cm⁻¹ explained the presence of BO₃ in these structures (Lemanceau et al. 1999). For borates and calcite and aragonite structures, the boron atoms are threefold coordinated (Chadeyron et al. (1997b)). The only calcite containing phase is LuBO₃ which has also vaterite phase in the structure. As shown in its IR spectrum (Figure C.3h.) the bands between 1350 and 1150 cm⁻¹ corresponds to BO₃ groups in the structure.

Figure 3.24. FT-IR spectrum of LaBO₃

Figure 3.25. FT-IR spectrum of SmBO₃

The rest of the orthoborates LnBO_3 ($\text{Ln}=\text{Y}, \text{Gd}, \text{Tb-Yb}$) have single phase according to XRD phase analysis. They have vaterite type of structure. According to IR, NMR, and Raman studies (Laperches and Tarte 1966, Denning and Ross 1972, Kriz and Bray 1969), these compounds contain only the tetrahedral polyborate group of $\text{B}_3\text{O}_9^{9-}$ in their structure and this structure contains BO_4 groups not BO_3 anions.

Therefore, the bands between $1150\text{-}1350\text{ cm}^{-1}$ are not seen in the FTIR spectra of YBO_3 and LnBO_3 ($\text{Ln}=\text{Gd}, \text{Tb}, \text{Dy}, \text{Ho}, \text{Er}, \text{Tm}, \text{Yb}$) in the Figure 3.26. and C.3.(a-g), respectively. The IR absorption peaks between 900 and 1050 cm^{-1} are those typical for the tetrahedral borate group BO_4 (Ren et al. 1999) and our results are consistent with these and LnBO_3 ($\text{Ln}=\text{Y}, \text{Gd}, \text{Tb-Yb}$) products is composed of $\text{B}_3\text{O}_9^{9-}$ in their structure.

Figure 3.26. FT-IR spectrum of YBO_3

3.4.3. Results of Rietveld Refinement Structural Analysis

The proper space group and the corresponding atomic positions either from ICSD database, CIF (Crystallographic Information Files) Files, or from references in the literature were tried to find the best crystallographic starting point for the rare earth orthoborates. Structure refinements were carried out using the XRD data and we used the Rietveld refinement program contained in the GSAS suite (Larson et al. 2000) for all refinements.

The Bragg peak profile was modeled using a pseudo-Voigt function. The instrumental background was empirically fitted using a cosine series polynomial of the second kind with 7 variable coefficients. The 2 theta-zero shift was accurately refined in all the patterns of the data set. One scale factor and the unit-cell parameters were allowed to vary for all histograms.

As anticipated, a tentative structure refinement using the structure model given in Lin et al. (2004) was also attempted for the structure of YBO_3 , DyBO_3 and HoBO_3 and their crystal structure is found in monoclinic system with $C2/c$ space group. The structure refinements with the $P63/m$, $P63/mmc$, $C2/c$ and $R3_2$ models have been performed comparatively in a rigorous way using the same data set for LnBO_3 (where $\text{Ln} = \text{Y, Dy, Ho}$). The scale factor, the unit cell parameters and the structure parameters were independently refined whereas the background and peak profile parameters were kept identical in the two refinements to rule out any possible correlation. The most probable space group for the produced YBO_3 , DyBO_3 and HoBO_3 compounds is found as $C2/c$. For YBO_3 , Co sourced STOE STADI-P Diffractometer was used to see any preferred orientation by using transmission geometry and no preferred orientation was observed as seen in Figure A.2. The similar d-spacing values were also observed with other diffractometer (Table B.15.)

As mentioned before, LaBO_3 and NdBO_3 compounds produced in this study have aragonite structure with $Pnma$ space group, while SmBO_3 has triclinic structure

with *P-1* space group. The produced GdBO₃ structure was solved according to Ren et al. (1999) with *R3₂* space group.

In the light of refinement results carried out to determine the most probable space group for the other rare earth borates LnBO₃ (Ln= Eu, Tb, Er, Tm, Yb, Lu) having vaterite structure but proper solution could not be found. The structural problem of all vaterite type of compound is due to their high and low temperature forms and the transition between these structures. Generally, the high temperature phase is *P6₃/mmc*. They are not quenchable compounds. They formed mixed of several space groups during cooling.

The reason for different space groups and why ErBO₃, TmBO₃, YbBO₃, LuBO₃ are problematic are lanthanides ionic radius. Since the ionic radius of Y (0.893 Å), Ho (0.894 Å), and Dy (0.908 Å) are close to each other, YBO₃, HoBO₃, DyBO₃ form the same space group *C2/c*. From Y to Dy and then to Ho, unit cell parameters are also increasing. For La (1.016 Å) and Nd (0.995 Å) which have the largest ionic radius among lanthanides, LaBO₃ and NdBO₃ have same orthorhombic *Pnma* space group. For Gd (0.938 Å), ionic radius is larger than Y, Ho, and Dy and this could be the reason of why GdBO₃ has different *R3₂* space group. Eu (0.950 Å) and Sm (0.964 Å) have relatively larger ionic radius than Gd and Y, Ho, and Dy and smaller than La and Nd. This also could be reason why EuBO₃ and SmBO₃ have triclinic *P-1* space group in their structure. The rest Er (0.881 Å), Tm (0.87 Å), Yb (0.858 Å), Lu (0.85 Å) have smallest ionic radius among lanthanides which could be reason why ErBO₃, TmBO₃, YbBO₃, LuBO₃ are not stable in one of these space groups mentioned above. Since the ionic radius of Er, Tm, Yb, Lu are so small, they probably enter many sites in different space groups making them having many space groups. They are not stable in definite space group (Weast 1977).

3.4.3.1. Structures of YBO₃, DyBO₃ and HoBO₃ with C2/c Space Group

Chadeyron et al. (1997) revised the structure of YBO₃ orthoborate. They achieve to synthesize YBO₃ single crystals by using LiBO₂ flux and they found that YBO₃ crystallize in *P6₃/m*. The same space group found and were given for YbBO₃ synthesized by glycothermal method (Hosokawa et al. 2008). We use these data for the refinements at the beginning. Although refinements seems converges at the beginning the intensity order of this space group totally different than the produced phase. This creates differences in difference plot curves. So, we decided to apply C2/c space group which was done for YBO₃ in neutron and did not tried for X-ray Diffraction before. The refinement converges with good residual values.

The results of the Rietveld refinement of YBO₃ are summarized in Table 3.11., and the corresponding profiles are shown in Figure 3.27. The difference curve given in Figure 3.27. and the matching of calculated lines with observed lines shows this model fitted well including intensity matches which means that proposed crystallographic structure is correct. The difference curve is resulted from intensity differences. The calculated lines are calculated by GSAS program (Larson et al. 2000). The refinement converged smoothly and the calculated goodness-of-fit parameters ($\chi^2=(R_{wp}/R_{exp})^2$) remained low ($\chi^2= 3.289$) showing good fit and chemically reasonable structure. The overall value of goodness-of-fit (χ^2) is obviously better than 12.7 given in Lin et al. (2004) showing good fit for this model. The summary of (Y_{0.92}Er_{0.08})BO₃ Rietveld refinement results and corresponding atomic structures were tabulated in Table 3.12.

The refined unit cell parameters for YBO₃ at room temperature are a=11.3276(3), b=6.5444(2) Å, c=9.5589(1) Å, $\beta=112.955(1)^\circ$, V=652.512 (9)Å³. The refinement leads to the residual values of R_p=0.0301, R_{wp}=0.0421 which are good agreement with the reported data.

The final atomic coordinates and the equivalent isotropic displacement parameters for YBO_3 given in Table 3.13. These data are in consistency with the data given in Table 3.12. The selected bond length and angles of monoclinic $C2/c$ were demonstrated in Table 3.14. In the YBO_3 structure, the B-O distances were found between 1.13915(3) Å and 1.995(5) Å, respectively. The Y-O bond distances are in between 2.22027(5) Å and 2.53378(4) Å. The three O-B-O angle were found as 108.003(1)°, 119.369(1)° and 112.102(3)°. The atomic positions, bond lengths and angles between atoms in YBO_3 are in good agreement with the reported data (Lin et al. 2004).

These refinement results were used to draw crystal structure of YBO_3 by using Diamond (2000-2006) software and the structure is given in Figure 3.28. The same structure with Lin et al. (2004) was obtained and $\text{B}_3\text{O}_9^{9-}$ anions are seen in this monoclinic cell.

The same space group $C2/c$ is tried for DyBO_3 and HoBO_3 and refinement converges with good residual values which were given in Table E.1. and E.2, respectively. It is found 1.96 and 3.968 for χ^2 values for DyBO_3 and HoBO_3 showing a good fit and chemically reasonable structure. The difference curves for these orthoborates were given in Figure A.3. and A.4., respectively. The same behaviour of good match with the calculated models are seen in these figures. The final atomic coordinated and the equivalent isotropic displacement parameters for DyBO_3 given in Table E.7. and E.8., respectively. The selected bond length and distances of these monoclinic compounds $C2/c$ were demonstrated in Table E.14. E.15. respectively. And the corresponding crystal structures were drawn in Figure F.1 and F.2., respectively. In these figures, monoclinic cell with $\text{B}_3\text{O}_9^{9-}$ anions are shown. These crystal structures are same with YBO_3 crystal structure.

Figure 3.27. Observed, calculated and difference X-ray diffraction profile for YBO_3 with approximate intensity scale depending upon the angular area. Crosses indicate the observed data and the solid line shows the calculated profile. All possible Bragg reflections are indicated with vertical markers below the profile.

3.4.3.2. Structures of LaBO₃, and NdBO₃ with Pnma Space Group

According to structural model of NdBO₃ (ICSD Card No: 01-041-2407) we refined the structure parameters of LaBO₃ and NdBO₃ from the X-ray diffraction data by Rietveld method using the computer program GSAS. Figure A.5. and the Figure A.6. shows the Rietveld refinement results for LaBO₃ and NdBO₃, respectively.

The results of the Rietveld refinements of LaBO₃ and NdBO₃ are summarized in Table E.3. and Table E.4., respectively. The refinements converged smoothly as seen in Figure A.5. and A.6. The LaBO₃ crystallize in orthorhombic system with the following refined unit cell parameters at room temperature $a=5.8761(1)$ Å, $b=5.10535(9)$ Å, $c=8.252(1)$ Å. The refinement leads to the residual values of $R_p=0.0844$, $R_{wp}=0.1076$ and $\chi^2= 5.101$. Since Müller-Bunz et al. (2003) synthesized single crystal product, we can not compare the residual values which is always lower than X-ray diffraction results but these values are quite reasonable. χ^2 value 5.101 seems quite higher but this is resulted from using NdBO₃ data for LaBO₃ indexing which is quite larger in atomic size. The residual values of NdBO₃ are $R_p=0.0691$, $R_{wp}=0.0544$ and $\chi^2=1.958$ with better fit to the Muller-Bunz structural model (Table E.4.).

The final atomic coordinates and the equivalent isotropic displacement parameters for orthorhombic LaBO₃ and NdBO₃ given in Table E.9. and Table E.10., respectively. These final positions are quite similar with the values given in ICSD Card No: 01-041-2407. The selected bond length and angles of orthorhombic lanthanide and neodymium orthoborates were demonstrated in Table E.16. and Table E.17. While the B-O distances were found between $1.35(1)$ Å and $1.40(3)$ Å for LaBO₃ structure, the very similar bonds lengths found as $1.352(5)$ Å and $1.40685(2)$ Å for NdBO₃. The Nd-O bond distances are in between $2.22027(5)$ Å and $2.53378(4)$ Å. The two O-B-O angle were found as $117.0(1)^\circ$ and $122.6(2)^\circ$ for LaBO₃ structure.

The crystal structure of LaBO_3 and NdBO_3 were obtained from these refinement results and crystal structures were given in Figure 3.29. and Figure F.3., respectively, by using Diamond (2000-2006). Trigonal BO_3 anions are easily seen in this orthorhombic structure.

Figure 3.29. The crystal structure of LaBO_3 . (Blacks: La atoms, Blues: B atoms, Reds: O atoms)

3.4.3.3. Structure of SmBO₃ P-1 with Space Group

By using the structural model given in SmBO₃ (ICSD Card No: 01-040-0745) we refined the structure parameters of our products from the X-ray diffraction data by Rietveld method using the computer program GSAS. The Rietveld refinement profile for triclinic SmBO₃ is given Figure A.7.

The results of the Rietveld refinements of SmBO₃ are summarized in Table E.5. The refinements converged smoothly as seen in Figure A.7. The SmBO₃ crystallize in triclinic system with the following refined unit cell parameters at room temperature $a=6.4904(3)$ Å, $b=6.4962(3)$ Å, $c=6.2431(3)$ Å, $\alpha=107.764(3)$ °, $\beta=107.703(3)$ °, $\gamma=93.385(2)$ °. The space group of SmBO₃ is *P-1*. The refinement leads to the residual values of $R_p=0.0532$, $R_{wp}=0.0682$ and $\chi^2=3.227$. The residual values of triclinic samarium orthoborate fit better with the structural model given in ICSD Card No: 01-040-0745.

The final atomic coordinates and the equivalent isotropic displacement parameters for orthorhombic SmBO₃ given in Table E.11. These final positions are quite similar with the values given in ICSD Card No: 01-040-0745. The selected bond length and angles of SmBO₃ orthoborate were demonstrated in Table E.18. The six B-O bond distances were found between $1.13935(3)$ Å and $1.995(5)$ Å for triclinic system while the Sm-O bond distances are in between $2.21042(6)$ Å and $3.00654(14)$ Å. The two O-B-O angles were found in between $91.045(3)$ ° and $130.750(2)$ °.

Figure 3.30. shows the crystal structure of triclinic SmBO₃ along *c* direction. The trigonal BO₃ groups can be seen from the figure. The samarium is in nine coordination in the triclinic cell.

Figure 3.30. Crystal structure of SmBO₃ (Blacks: Sm atoms, Blues: B atoms, Reds: O atoms)

3.4.3.4. Structure of GdBO₃ with R3₂ Space Group

Since the space group work of vaterite structure is problematic, we used the all possible space groups mentined before to find out the best possible space group All attempts were failed and the refinements generally diverges for other space groups for GdBO₃. Only possible space group is R3₂ as mentioned in Ren et al. (1999).

Ren et al. (1999) reported the structure of GdBO₃ orthoborate structure. In this work, the phase purity of GdBO₃ powder samples was examined by X-ray diffraction. They derived the rhombohedral lattice constants from electron diffraction and refined from X-ray diffraction pattern, are $a=6.6357(2)$ Å and $c=26.706(1)$ Å. Ren et al. (1999) could not identify the boron atoms from the refinement, because their scattering power is too small. They were inserted into the structure by considering the structure of the polyborate group B₃O₉⁹⁻. The unit cell values and the atomic positions given in Table E.12. were used as a structural model for our GdBO₃ product. The refinement converged and the calculated goodness-of-fit parameters remained low ($\chi^2= 2.590$) showing good fit and chemically reasonable structure. The refined unit cell parameters for GdBO₃ at room temperature are $a=6.63899(8)$, $c=26.7219(5)$ Å for our case.

Table E.6 summarized the results of the Rietveld refinement and the corresponding profiles are shown in Figure A.8. The differeence plot are very similar to profile given in Ren et al. (1999) and the same difference curve was obtained in this work. Their refinement leads to the residual value of $R_p=0.12$ and $R_{wp}=0.16$, while same residuals were found as $R_p=0.032$ and $R_{wp}=0.0454$. When we compare the better residual values with the literature ones, one can easily see that this hexagonal model was fitted well.

The final atomic coordinates and the equivalent isotropic displacement parameters for GdBO₃ given in Table E.13.

The selected bond lengths and angles of rhombohedral $R\bar{3}2$ cell were demonstrated in Table E.19. In the GdBO_3 structure, the B-O distances were found as 1.28037(2) Å, 1.68689(1) and 1.75480(1) Å, respectively. The Gd-O bond distances are in between 2.21827(2) Å and 2.54225(3) Å. The O-B-O angle were found between 103.580(1) ° and 143.991(1) °. Diamond (2000-2006) software program was used to draw crystal structure of GdBO_3 and the structure is given in Figure 3.31. The long c-cell and the $\text{B}_3\text{O}_9^{9-}$ anions can be derived from the structure. This structure was solved from the diffraction and it is very similar to the structure (Figure 1.12.) represented by Ren et al. (1999) in section 1.3.2.

Figure 3.31. Shows the crystal structure of GdBO_3 (Blacks: Gd atoms, Blues: B atoms, Reds: O atoms)

CHAPTER 4

CONCLUSIONS AND RECOMMENDATIONS

Borate and phosphate compounds are currently very attractive to the scientific community owing to their wide range of applications. In this thesis, it was aimed to synthesize and characterize sodium lanthanide oxide phosphates, rare earth added strontium pyrophosphates and rare earth orthoborates. It was shown for the first time in this study that new orthorhombic lanthanide oxide phosphates were synthesized; thermoluminescence and structural studies of rare earth added $\text{Sr}_2\text{P}_2\text{O}_7$ were applied; LnBO_3 (Ln= La, Nd, Dy, Ho) were synthesized by using microwave-assisted solid state synthesis with submicron particle sizes; and structural determination of all rare earth borates (Ln=Y, La-Lu) were investigated via Rietveld refinement. In the light of experimental test results obtained at the end of this investigation, the following conclusions can be driven:

1. In the first set of sodium lanthanide oxide phosphate compounds, $\text{Na}_2\text{LaOPO}_4$, $\text{Na}_2\text{NdOPO}_4$, and $\text{Na}_2\text{SmOPO}_4$ have unit cell parameters of $a=13.60(1)$, $b=12.71(1)$, $c=6.96(1)$; $a=13.466(5)$, $b=12.547(6)$, $c=6.932(5)$; $a=13.54(1)$, $b=12.577(8)$, $c=7.047(5)$ Å, respectively and the space group is *Pmm2*. The splitting of the peaks in the X-ray diffraction patterns was observed in all compounds in the first set at $d=3.35$ and 3.30 Å, $d=3.29$ and 3.25 Å, $d=3.29$ and 3.25 Å, respectively. By the help of the same procedure, new orthorhombic $\text{Na}_2\text{DyOPO}_4$, $\text{Na}_2\text{HoOPO}_4$, $\text{Na}_2\text{ErOPO}_4$, and $\text{Na}_2\text{YbOPO}_4$ were synthesized the first time in the literature at 1100 °C. The indexing of the data showed that $\text{Na}_2\text{GdOPO}_4$ and the new products are also orthorhombic with the unit cell parameters $a=13.37(1)$, $b=12.775(9)$, $c=6.910(9)$; $a=13.66(2)$, $b=12.609(9)$, $c=6.611(6)$; $a=13.148(4)$, $b=12.577(2)$, $c=6.967(1)$;

$a=13.563(5)$, $b=12.604(4)$, $c=7.003(3)$; $a=13.501(7)$, $b=17.579(9)$, $c=6.729(4)$ Å for $\text{Na}_2\text{DyOPO}_4$, $\text{Na}_2\text{HoOPO}_4$, $\text{Na}_2\text{ErOPO}_4$, and $\text{Na}_2\text{YbOPO}_4$, respectively and the space group of this set is also $Pmm2$. However, splitting of X-ray diffraction peaks between $d=3.35$ and 3.30 Å were not observed throughout the second set. If the single crystals of these compounds would be obtained, structural results will be more reliable.

2. The orthorhombic $\text{Sr}_2\text{P}_2\text{O}_7$ were obtained by solid state reaction with $a=8.900(2)$, $b=13.151(2)$, and $c=5.402(2)$ Å unit cell parameters. The unit cell parameters of the other samples were fluctuated in between $a=8.909(5)$ - $8.877(5)$, $b=13.163(3)$ - $13.12(1)$, and $c=5.403(2)$ - $5.386(4)$ Å. The cubic ZrP_2O_7 ($a=24.74(1)$ Å) addition is the reason for these changes. The glow curves of the $\text{Sr}_2\text{P}_2\text{O}_7$ added with ZrP_2O_7 exhibit one strong glow peak at around 100 °C. The intensity of prominent glow peak at 100 °C is continuously increased with decreasing concentration of ZrP_2O_7 among the set 2. The TL sensitivity of these samples when compared with the well known dosimetric material LiF:Mg,Ti (TLD-100) are much more than TLD-100.
3. XRD studies of 5% CuO and rare earth oxides (Y_2O_3 , La_2O_3 , CeO_2 , Pr_6O_{11} , Nd_2O_3 , Sm_2O_3 , Eu_2O_3 , Gd_2O_3 , Tb_2O_3 , Dy_2O_3 , Ho_2O_3 , Er_2O_3 , Tm_2O_3 , Yb_2O_3 , Lu_2O_3) 0.5-15% (by weight) added $\text{Sr}_2\text{P}_2\text{O}_7$ showed that addition did not affect our host structure but only small shifts observes in XRD patterns of added samples. The TL glow curve of pure $\text{Sr}_2\text{P}_2\text{O}_7$ consists of only one glow peak at around 100 °C [Seyyidođlu et al (2007)]. On the other hand, Pr, Ho, and Nd along with Cu-added samples showed two glow peaks, one of them is always at around 90 °C and the second TL peak around 180 , 275 , and 285 °C, respectively. So, it can be thought that the first peak at ≈ 90 °C in all samples should be related with host samples but the second peak above 150 °C with the added elements.

As a conclusion, this work investigated the TL properties of $\text{Sr}_2\text{P}_2\text{O}_7$ which is added with rare-earth oxides series and CuO together. Many of the results gave TL glow curves but not so intense and no glow peaks around 200 °C. Yet, Pr, Nd, Ho, and Er along Cu-added samples resulted with very intense, sharp peaks in TL glow curves around 200 °C. In order to investigate effect of different metal oxides addition on the TL properties of $\text{Sr}_2\text{P}_2\text{O}_7$, various metal oxides will be added together with rare earth metal oxides.

4. XRD studies revealed that while LaBO_3 and NdBO_3 samples prepared by both solid state and microwave-assisted synthesis with urea and sucrose has the same orthorhombic crystal structure with *Pnma* (aragonite-type) space group, the DyBO_3 and HoBO_3 orthoborates has hexagonal crystal structure with space group of *P-6c2* (vaterite-type). It is obviously seen that particles has submicron ($<1\mu\text{m}$) size, most of them has around 500 nm particle size in diameter and homogenously distributed for samples prepared by urea and sucrose. The particle sizes of direct solid state products are larger than $1\mu\text{m}$ and particles have not equal size and the distribution is random. This microwave irradiation method, with using cheap microwave active organic additives such as sucrose and urea and requiring no expensive equipments, will ensure good purity in the products, reduce the particle size of products and greatly reduce the production cost, and will thus offer a simple and rapid synthetic route for other functional inorganic materials. The effects of various microwave active organic molecules on the structure and the size of rare earth orthoborate particles can be investigated in future.
5. YBO_3 crystallize in monoclinic system at room temperature with the unit cell parameters of $a=11.3276(3)$, $b=6.5444(2)$ Å, $c=9.5589(1)$ Å, $\beta=112.955(1)^\circ$, $V=652.512(9)$ Å³ with the *C2/c* space group. The overall value of goodness-of-fit (χ^2) 3.289 is obviously better than 12.7 given in Lin et al. (2004) showing good fit for this model.

The same space group $C2/c$ is tried for $DyBO_3$ and $HoBO_3$ and it is found 1.96 and 3.968 for χ^2 values for $DyBO_3$ and $HoBO_3$ showing a good fit and chemically reasonable structure.

6. The $LaBO_3$ crystallize in orthorhombic system (Pnma) with the following refined unit cell parameters at room temperature $a=5.8761(1)$ Å, $b=5.10535(9)$ Å, $c=8.252(1)$ Å. The refinement leads to the residual values of $R_p=0.0844$, $R_{wp}=0.1076$ and $\chi^2 = 5.101$ while the residual values of $NdBO_3$ are $R_p=0.0691$, $R_{wp}=0.0544$ and $\chi^2=1.958$ with better fit to the Muller-Bunz (2003) structural model.
7. The $SmBO_3$ crystallize in triclinic system with the following refined unit cell parameters at room temperature $a=6.4904(3)$ Å, $b=6.4962(3)$ Å, $c=6.2431(3)$ Å, $\alpha=107.764(3)^\circ$, $\beta=107.703(3)^\circ$, $\gamma=93.385(2)^\circ$. The space group of $SmBO_3$ is $P-1$. The refinement leads to the residual values of $R_p=0.0532$, $R_{wp}=0.0682$ and $\chi^2=3.227$. The residual values of triclinic samarium orthoborate fit better with the structural model given in ICSD Card No: 01-040-0745.
8. The refined unit cell parameters for $GdBO_3$ at room temperature were found as $a=6.63899(8)$, $c=26.7219(5)$ Å. Ren et al. (1999) find the residuals as $R_p=0.12$ and $R_{wp}=0.16$, while same residuals were found as $R_p=0.032$ and $R_{wp}=0.0454$ for our product showing better fit for this $R3_2$ rhombohedral model. All of rare earth orthoborate structures will be confirmed by synthesizing single crystals of these compounds and making single crystal structural analysis.

APPENDIX A

XRD PATTERNS OF THE PRODUCED PHASES

Individual XRD patterns of the produced phases from the solid state reactions are presented in the following figures.

Figure A.1. X-Ray Diffraction Pattern of a) TbBO₃, b) ErBO₃, c) TmBO₃, d) YbBO₃, e) LuBO₃ Scanned by Using Panalytical Diffractometer.

Figure A.2. X-Ray Diffraction Pattern of YBO_3 Scanned by Using STOE STADI-P Diffractometer.

Figure A.3. Observed, calculated and difference X-ray diffraction profile for DyBO₃ with approximate intensity scale depending upon the angular area. Crosses indicate the observed data and the solid line shows the calculated profile. All possible Bragg reflections are indicated with vertical markers below the profile.

Figure A.4. Observed, calculated and difference X-ray diffraction profile for HoBO_3 with approximate intensity scale depending upon the angular area. Crosses indicate the observed data and the solid line shows the calculated profile. All possible Bragg reflections are indicated with vertical markers below the profile.

Figure. A.5. Observed, calculated and difference X-ray diffraction profile for LaBO₃ with approximate intensity scale depending upon the angular area. Crosses indicate the observed data and the solid line shows the calculated profile. All possible Bragg reflections are indicated with vertical markers below the profile.

Figure A.6. Observed, calculated and difference X-ray diffraction profile for NdBO₃ with approximate intensity scale depending upon the angular area. Crosses indicate the observed data and the solid line shows the calculated profile. All possible Bragg reflections are indicated with vertical markers below the profile.

Figure A.7. Observed, calculated and difference X-ray diffraction profile for SmBO_3 with approximate intensity scale depending upon the angular area. Crosses indicate the observed data and the solid line shows the calculated profile. All possible Bragg reflections are indicated with vertical markers below the profile.

Figure A.8. Observed, calculated and difference X-ray diffraction profile for GdBO₃ with approximate intensity scale depending upon the angular area. Crosses indicate the observed data and the solid line shows the calculated profile. All possible Bragg reflections are indicated with vertical markers below the profile.

APPENDIX B

XRD DATA OF THE PRODUCED PHASES

The following tables represent the XRD data of the produced phases.

Table B.1. X-ray Diffraction Data of Na₂LaOPO₄ (a=13.60(1), b=12.71(1), c=6.96(1) Å) (Intensities over 5 were given).

d_{obs} (Å)	d_{cal} (Å)	$(I/I_o)_{\text{obs}}$	h k l	d_{obs} (Å)	d_{cal} (Å)	$(I/I_o)_{\text{obs}}$	h k l

APPENDIX C

INFRARED AND RAMAN SPECTRA OF THE PRODUCED PHASES

The separate FTIR and Raman spectrum and tables for produced compounds at different conditions are demonstrated in this section.

Figure C.1. FT-IR spectrum of NdBO₃.

Figure C.2. FT-IR spectrum of EuBO₃.

Figure C.3. FT-IR spectra of a) GdBO₃, b) TbBO₃, c) DyBO₃, d) HoBO₃, e) ErBO₃, f) TmBO₃, g) YbBO₃, h) LuBO₃.

APPENDIX D

SEM MONOGRAPHS and EDX ANALYSIS OF PRODUCED PHASES

The surface morphology of $\text{Sr}_2\text{P}_2\text{O}_7$ and ZrP_2O_7 compounds synthesized by solid state reaction are demonstrated in SEM pictures given in the following figures. The composition of ZrP_2O_7 , 10% $\text{Sr}_2\text{P}_2\text{O}_7$ added ZrP_2O_7 , $\text{Sr}_2\text{P}_2\text{O}_7$, and 10% ZrP_2O_7 added $\text{Sr}_2\text{P}_2\text{O}_7$ compounds given in EDX spectrum.

a. ZrP_2O_7

b. $\text{Sr}_2\text{P}_2\text{O}_7$

APPENDIX E

CRYSTAL DATA, STRUCTURE REFINEMENT RESULTS, ATOMIC POSITIONS, SELECTED BOND LENGTHS AND DISTANCES OF NdBO₃, DyBO₃, HoBO₃

The crystal system, space group, residual rietvel values, and unit cell parameters of NdBO₃, DyBO₃, HoBO₃ compounds were given in crystal data and structure refinement results. Atomic positions, the bond lengths and distances of these compounds were given.

Table E.1. Crystal data and structure refinement results for DyBO₃.

Empirical Formula	DyBO ₃
Molar mass	221.3 g/mol
Crystal System	Monoclinic
Space Group	<i>C2/c</i>
Powder diffractometer	Panalytical X'Pert Pro
Radiation	CuK α 1(λ =1.54051Å)
Unit-cell dimensions	a=11.3708(6) Å b=6.5718(3) Å c=9.6012(2) Å β =112.922(2)°
Volume	660.80(1) Å ³
Step (°)	0.013
2 Theta Range	10-150°
R _{wp}	0.036
R _p	0.027
χ^2	1.96

Table E.2. Crystal data and structure refinement results for HoBO₃.

Empirical Formula	HoBO ₃
Molar mass	223.7 g/mol
Crystal System	Monoclinic
Space Group	<i>C2/c</i>
Powder diffractometer	Panalytical X'Pert Pro
Radiation	CuK α 1(λ =1.54051Å)
Unit-cell dimensions	a=11.3317(4) Å b=6.5475(3) Å c=9.5749(2) Å β =112.944(1)°
Volume	654.20(1) Å ³
Step (°)	0.013
2 Theta Range	10-150°
R _{wp}	0.0581
R _p	0.0421
χ^2	3.968

Table E.3. Crystal data and structure refinement results for LaBO₃.

Empirical Formula	LaBO ₃
Molar mass	197.7 g/mol
Crystal System	Orthorhombic
Space Group	<i>Pnma</i>
Powder diffractometer	Panalytical X'Pert Pro
Radiation	CuK α ($\lambda=1.54051\text{\AA}$)
Unit-cell dimensions	a=5.8761(1) \AA b=5.10535(9) \AA c=8.252(1) \AA
Volume	247.570 (8) \AA^3
Step ($^{\circ}$)	0.013
2 Theta Range	10-150 $^{\circ}$
R _{wp}	0.1076
R _p	0.0844
χ^2	5.101

Table E.4. Crystal data and structure refinement results for NdBO₃.

Empirical Formula	NdBO ₃
Molar mass	203.1 g/mol
Crystal System	Orthorhombic
Space Group	<i>Pnma</i>
Powder diffractometer	Panalytical X'Pert Pro
Radiation	CuK α 1(λ =1.54051Å)
Unit-cell dimensions	a=5.73221(7) Å b=5.04199(6) Å c=8.0833(1) Å
Volume	233.621(3) Å ³
Step (°)	0.013
2 Theta Range	10-150 °
R _{wp}	0.0691
R _p	0.0544
χ^2	1.958

Table E.5. Crystal data and structure refinement results for SmBO₃.

Empirical Formula	SmBO ₃
Molar mass	209.2 g/mol
Crystal System	Triclinic
Space Group	<i>P</i> -1
Powder diffractometer	Panalytical X'Pert Pro
Radiation	CuK α (λ =1.54051Å)
Unit-cell dimensions	a=6.4904(3) Å b=6.4962(3) Å c=6.2431(3) Å α =107.764(3) ° β =107.703(3) ° γ =93.385(2) °
Volume	235.437 (7) Å ³
Step (°)	0.013
2 Theta Range	10-150 °
R _{wp}	0.0682
R _p	0.0532
χ^2	3.227

Table E.6. Crystal data and structure refinement results for GdBO₃.

Empirical Formula	GdBO ₃
Molar mass	216.1 g/mol
Crystal System	Rhombohedral
Space Group	<i>R</i> 3 ₂
Powder diffractometer	Panalytical X'Pert Pro
Radiation	CuK α (λ =1.54051Å)
Unit-cell dimensions	a=6.63899(8) Å c=26.7219(5) Å
Volume	1020.00 (2) Å ³
Step (°)	0.013
2 Theta Range	10-150 °
R _{wp}	0.0454
R _p	0.0320
χ^2	2.590

O3-B6-O4	128.210(1)	O3-B6-O3	103.580(1)

Distances are given in Å and angles in degrees (°).

APPENDIX F

CRYSTAL STRUCTURES OF NdBO₃, DyBO₃, HoBO₃

Three dimensional crystal structures of NdBO₃, DyBO₃, HoBO₃ are demonstrated in this section.

Figure F.1. Crystal structure of DyBO₃ (Blacks: Dy atoms, Blues: B atoms, Reds: O atoms).

Figure F.2. Crystal structure of HoBO₃ (Blacks: Ho atoms, Blues: B atoms, Reds: O atoms).

Figure F.3. Crystal structure of NdBO₃ (Blacks: Nd atoms, Blues: B atoms, Reds: O atoms).

CURRICULUM VITAE

Surname, Name: Seyyidođlu, Semih
Nationality: Turkish (TC)
Date and Place of Birth: 19 July 1977, Istanbul
Marital Status: Married
Phone: +90 312 210 32 10
Fax: +90 312 210 32 00
e-mail: semihseyyidoglu@yahoo.com

EDUCATION

Degree	Institution	Year of Graduation
Ph.D.	METU, Chemistry Department	2009
MSc.	METU, Chemistry Department	2003
BS	METU, Chemistry Department	2001

WORK EXPERIENCE

Year	Place	Enrollment
2009-	Seyyidoglu Ultrasonic Solutions	Owner
2007-2008	Panalytical, TETRA	XRD Specialist
2001-2007	Chemistry Department	Research Assistant

AWARDS

2007 June Full Scholarship for ICDD- XRD Clinics 1&2 Education

MEMBERSHIPS

2002-2007 Member of *Executive* Board Turkey Chemistry Association, Ankara, Turkey

2007-present Member of Chemists Society, Izmir, Turkey

2009-present Member of American Chemical Society, Washington DC, USA

FOREIGN LANGUAGES

Advanced English, Good Russian

International Conference Presentations:

1. “Structural Investigations of $LnBO_3$ ($Ln= Y, La, Nd, Sm, Eu, Gd, Dy, Ho, Er, Yb, Lu$) by Rietveld Method”, Seyyidoglu S, Hoffmann K., Albert B., Yilmaz A., ECM-25 European Crystallography Meeting-25, Istanbul, Turkey, August, 2009.

2. "Formation of Conducting Micro-Nanostructures of Carbon from Poly(Hydridocarbyne) Synthesized Via Electro-polymerization", Aaron M. Katzenmeyer¹, Yavuz Bayam^{1,2}, Logeeswaran VJ¹, Michael W. Pitcher³, Yusuf Nur³, Semih Seyyidođlu³, Levent K. Toppare³, A. Alec Talin⁴ and M. Saif Islam¹, IEEE Nanotechnology Conference, Texas, USA, August, 2008.
3. "Electrically produced polycarbynes: Polymeric precursors to diamond and diamond-like carbon", Michael W. Pitcher, Yusuf Nur, Semih Seyyidođlu, Asli Tařkın, Halime Cengiz, Levent Toppare, Poster Presentation at American Chemical Society 234th National Meeting & Exposition, Boston, USA, August, 2007.
4. "Controlling the crystallization of calcium carbonate: Metastable vaterite formation using a polymer matrix", Michael W. Pitcher, Abdollah Neshat, Semih Seyyidođlu, Poster Presentation at American Chemical Society 234th National Meeting & Exposition, Boston, USA, August, 2007.
5. "Synthesis and Characterization of Speciality Boron Products Produced by Microwave Energy", Seyyidoglu S., Aysen Yilmaz, Macit Ozenbas, Oral Presentation at the *3rd International Boron Symposium*, Ankara, Turkey, November , 2006.
6. "Factors Influencing Dispersion of Cobalt oxide Nanoparticles in Mesoporous Silica SBA-15", Aysen Yilmaz, Ersin Yildiz, Seyyidoglu S., Ebubekir Sen, Poster Presentation at the *Fifth International Conference on Inorganic Materials*, Ljubljana, Slovenia, September , 2006.
7. "Factors Influencing Dispersion of Cobalt oxide Nanoparticles in Mesoporous Silica SBA-15", Aysen Yilmaz, Ersin Yildiz, Seyyidoglu S., Ebubekir Sen, Oral Presentation at the *International Workshop on Nanostructured Materials*, Antalya, Turkey, June , 2006.
8. "Solid State Synthesis and Characterization of Some Novel Sodium Rare Earth Phosphates", Seyyidoglu S., Macit Ozenbas, Meral Kizilyalli, Aysen Yilmaz, Poster Presentation at the *XX Congress of International Union of Crystallography*, Florence, Italy, August, 2005.
9. "Synthesis and Characterization of Some Novel Borate Phosphates", Seyyidoglu S., Meral Kizilyalli, Poster Presentation at the *14th International Symposium on Boron, Borides and Related Compound*, St.Petersburg, Russian Federation, June, 2002.

National Conference Presentations

1. "Tailoring the morphology and particle size of BPO₄ by solvothermal and microwave assisted synthesis methods", Mehmet Kayhan, Semih Seyyidoglu, Ayřen Yılmaz, Nano-Tr-5, Ulusal Nano Teknoloji Kongresi, Eřiřehir, Haziran, 2009.

2. “Katı Hal Yöntemiyle Üretilen LnBO_3 (Ln= Y, La, Nd, Sm, Eu, Gd, Dy, Ho, Er, Tm, Yb, Lu) Serisinin Rietveld Analizi İle Yapısının İncelenmesi”, Semih Seyyidođlu, Ayşen Yılmaz, Oral Presentation at XXII. Ulusal Kimya Kongresi, Northern Cyprus, October, 2008.
3. “ Pb^{2+} Katkılı $\text{SrAl}_2\text{B}_2\text{O}_7$ Bileşiğinin Fotoluminesans Özelliklerinin İncelenmesi”, İlhan Pekgözlü, Semih Seyyidođlu, Sölin Taşcıođlu, Poster Presentation at X. Ulusal Spektroskopi Kongresi, İzmir, July, 2007.
4. “ Pb^{2+} Katkılı $\text{CaAl}_2\text{B}_2\text{O}_7$ Bileşiğinin Fotoluminesans Özelliklerinin İncelenmesi”, İlhan Pekgözlü, Semih Seyyidođlu, Sölin Taşcıođlu, Oral Presentation at Ulusal Teknik Eğitim, Mühendislik ve Eğitim Bilimleri Genç Araştırmacılar Sempozyumu(UMES 2007), Kocaeli, June, 2007.
5. “Nadir Toprak Elementi Katkılanmış $\text{Sr}_2\text{P}_2\text{O}_7$ Bileşiklerinin Sentezi, Karakterizasyonu ve Termoluminesans Özellikleri”, Seyyidođlu S., Necmeddin Yazıcı, Ayşen Yılmaz, Poster Presentation at the 1st National Inorganic Chemistry Days, Adana, Turkey, April, 2007.
6. “Single-step Direct Synthesis of Cobalt Incorporated Mesoporous Silica SBA-15”, Ayşen Yılmaz, Ebubekir Sen, Seyyidođlu S., and Jie Fan, Oral Presentation at the 1st National Catalysis Conference, Northern Cyprus, January, 2007.
7. “Nadir Toprak Elementi İçeren Boratların Mikrodalga ve Katı-Hal Yöntemiyle Sentezinin ve Karakterizasyonun İncelenmesi”, Seyyidođlu S., Macit Ozenbas, Ayşen Yılmaz, Poster Presentation at the XIX. National Chemistry Congress, Kusadası, Turkey, September, 2005.
8. “Borofosfatlı Bileşikler: Sentez ve Yapı Çalışmaları”, Seyyidođlu S., Ayşen Yılmaz, Meral Kızılyalli, Oral Presentation at the 2nd Boron Symposium, Zonguldak, Turkey, May, 2004.
9. “Bazı Yeni Zr ve Mo Borofosfatların Katı-Hal Yöntemiyle Eldesi ve Tanımlanması”, Seyyidođlu S., Meral Kızılyalli, Poster Presentation at the 1st Boron Symposium, Balıkesir, Turkey, June, 2002.
