STUDY OF HEAVY QUARKONIA SPECTRA IN THE QUARK MODEL

Takan, Taylan
M.Sc., Department of Physics
Supervisor : Prof. Dr. Altuğ Özpineci

February 2012, 51 pages

Conventional Heavy Quarkonium systems, Charmonium and Bottomonium, are believed to be composed of a heavy quark and anti-quark pair. These systems are investigated by different methods resulting from different approaches to Quantum Chromodynamics (QCD), such as Lattice QCD, Effective Theories and Sum Rules. In this thesis we study the spectrum of Charmonium and Bottomonium using a non-relativistic Quark Model. Assuming one gluon exchange for the short distances and a linear confining potential for long distances we derive Breit-Fermi interaction Hamiltonian and calculate the spectra arising from this Hamiltonian. Also we calculate the partial widths of E1 and M1 radiative decays.

Keywords: QCD, Quark Model, Charmonium, Bottomonium, Heavy Quarkonia

ACKNOWLEDGMENTS

I would like to express my deepest gratitude to my advisor, Prof. Dr. Altuğ Özpınecı not only for his support and guidance but also for motivating and helping me with his insight.

I am grateful to Prof. Dr. Mehmet T. Zeyrek for his constant guidance throughout my undergraduate and graduate years. Without his generous support, especially during the most challenging times, this thesis would not be possible.

I would like to thank fellow students, Nader Ghazanfari, Kamil Çınar, Baha Dinçel, Muhammed Miraç Serim, Sinan Değer, Ozan Yılırm, Selçuk Bilmiş, Utku Can, Ulaş Özdem, Vedat Tanrıverdi, Didem Çebi, Mehmet Ali Olpak and Deniz Devecioğlu for their company.

I would like to thank Ceren Sibel Sayın for patiently being with me throughout very hard years and devoting her support during the writing of this thesis.

I owe many thanks to my parents, Zuhal and Muslihittin Takan for their encouragement, support and understanding.

Quarks together with leptons constitute the ordinary matter content of our universe. Physics of quarks and the force carriers between them, gluons, is governed by Quantum Chromodynamics (QCD). Unlike Quantum Electrodynamics or the unified Electroweak theory, Quantum Chromodynamics does not readily supply us with physical observables such as the mass of the bound states of quarks and anti-quarks called hadrons nor the transitions between these different states.

This challenge presented by QCD can be attributed to the several features that are not present in other local gauge field theories. One of these characteristic properties is the non-Abelian nature of theory, resulting from the fact that the force carriers carry color charge themselves. Therefore in QCD one must consider interactions between the gauge bosons in addition to the interaction between fermions and the gauge bosons.

Apart from the non-Abelian nature one must also embark upon three important phenomena that QCD presents, namely, asymptotic freedom, confinement and dynamical breaking of chiral symmetry.

Asymptotic freedom of QCD dictates that the coupling constant, $\alpha_s$, depends on the momentum transfer in a process. For soft processes, which include low momentum exchange, $\alpha_s$ is large, therefore perturbation theory can not be used. $\alpha_s$ becomes small only at large momentum values. These processes are called hard processes. In terms of the momentum exchange, $Q^2$, the lowest order QCD corrections to $\alpha_s$ can be parameterized as,

$$\alpha_s(Q^2) = \frac{12\pi}{(33 - 2n_f) \ln(Q^2/\Lambda^2)}$$  \hspace{1cm} (1.1) 

where $n_f$ is the number of fermion flavors with mass below $Q$, and $\Lambda \approx \Lambda_{\text{QCD}}$ is the charac-
teristic scale of QCD measured as $\approx 200\text{MeV}$ [28]. Although it seems at first sight that hard processes can be calculated perturbatively, it is generally not the case and one needs further relation between partons and the observed hadrons and these relations, called structure and fragmentation functions, can not be calculated perturbatively. As an example; the decay of $c\bar{c}$ into gluons can be calculated perturbatively, however to calculate the annihilation of $J/\Psi$ into light hadrons one needs the wave function of the $c\bar{c}$ system at the origin, $\Psi(0)$, which is not calculable by the perturbation theory [32].

As mentioned above, for the low momentum exchange, or in other words for the long distances, the perturbation theory fails completely and we face a new phenomenon; confinement. Flux tube model gives a qualitative explanation of confinement. According to this model as the distance between quark and an anti-quark, or two quarks, increases the field lines bunch up to form a flux tube, resulting in a potential energy that depends approximately linearly on the distance,

$$\sim \sigma r$$  \hspace{1cm} (1.2)\]
characterized by the string constant, $\sigma$. If the distance, therefore energy is increased further a new quark-anti-quark pair forms resulting in total two colorless hadrons. Although as of now there is no satisfactory explanation of the confinement which is based solely on the QCD Lagrangian, there are several approaches that hints confinement. The lattice models are successful in simulating this phenomena and calculating the string tension [7]. On the theoretical side there is work in progress, which suggests that QCD potential may be expressed as Coulomb plus a linear potential [41].

The third important concept of QCD is the dynamical breaking of chiral symmetry. Symmetry breaking can be explained qualitatively by considering the QCD Lagrangian for $N$ quark flavors with massless quarks,

$$L = i\Sigma_\mu \bar{q} \left[ \partial_\mu - ig_s \sum_a \frac{1}{2} A^a_\mu \right] \gamma^\mu q_i - \frac{1}{4} \sum_a F^a_{\mu\nu} F^{a\mu\nu}$$  \hspace{1cm} (1.3)\]
where the mass term, $-\Sigma \bar{q} m q_i$, is dropped. In such a theory there is an exact chiral $SU(N) \times SU(N)$ symmetry but this symmetry breaks down to $SU(N)$ because of the non-vanishing expectation value of the QCD vacuum. The Goldstone bosons corresponding to this symmetry breaking are the pseudoscalar mesons.

To deal with the mentioned aspects of the QCD, different methods are available such as QCD sum rules, Effective Theories, Lattice QCD and AdS/QCD correspondence.
This thesis is concerned with the Quark Model approach. Compared with the other methods mentioned above Quark Model may seem inadequate as it lacks the rigor present in other models as Quark Model is based mostly on intuition and include bold assumptions. The answer to these concerns is that Quark Model works in it’s own domain, as proved by numerous studies [23].

Today with the experiments providing us greater precision on the spectrum and decay widths [45] more than ever and the discovery of the unconventional Ψ and Υ bound states [2][12], which can not be explained with the usual $q\bar{q}$ picture, the intuitive nature of Quark Model may leverage it’s use as a testing ground for new ideas.

The purpose of this thesis is to investigate the basic assumptions and intuitive picture behind the Quark Model. To serve this purpose we think that the Charmonium and Bottomonium spectra provides us an unique opportunity; we believe the study of low lying states that have been the subject of may fruitful analysis [18][17][19][43][27][36] can enable us to investigate the basic assumptions and newly found higher mass states and unconventional states [6][42] which are believed to fall outside the assumptions of the Quark Model may help draw the boundaries of the quark model or even expand them.
CHAPTER 2

QUARK MODEL

The physics of hadrons is multi-dimensional. When considering the spectroscopy we face increasing values of radius at excited state, which is dominated by non-perturbative effects, but when considering decays we deal with hard processes occurring at short distances which in part allows perturbative approach. Therefore the challenge before the Quark model is to describe a system with two different regimes. To accomplish this hard task the Quark Model, in its simplest form assumes that the interactions of quarks to be a two-body potential and quarks to be heavy enough that they satisfy the non-relativistic Schrodinger equation. In doing so it disregards the gluonic degrees of freedom in the QCD Lagrangian [32].

In the perturbative regime, the potential arising from QCD is simply Coulomblike, this follows from the fact that for small $\alpha_s$ we only need to consider one gluon exchange, as it will be the dominant process. One gluon exchange between a quark and an anti-quark have the same form as electron-anti-electron scattering which has the form of Coulomb interaction. This similarity between quarkonia and positronium allows heavy quarkonium physics to be a testing ground for QCD.

However this similarity holds only for short distances, and we are still left with the delicate question about of the form and the origin of the confining potential. In the early days of the Quark Model much debate has been made on the form of the confining potential [37]. Today we are closer more than ever to a complete description of the confinement and the form of the confining potential. The quantitative picture is provided mainly by the Lattice QCD calculations which predict a linear potential with the string tension around 0.15 GeV$^2$[30]. Other approaches confirm the form, if not the value the potential obtained from lattice simulations.
2.1 One-Gluon Exchange

To motivate the coulomb potential we begin by considering scattering of a quark from anti-quark. For the s-channel, using Feynman rules, we obtain,

\[-iM = \bar{u}(3)c_{3k}^\dagger\left(-i\frac{\alpha_s}{2}\bar{c}_{kl}\gamma^\mu\right) [c_{4l}v(4)] \left(-i\frac{g_{\mu\nu}\gamma^\rho}{q^2} \right) [\bar{v}(2)c_{2j}^\dagger]\left(-i\frac{\alpha_s}{2}\lambda_{ji}^\beta\gamma^\nu\right) [c_{1i}u(1)] \]

(2.1)

Therefore the s-channel amplitude is given by,

\[M = \left(\frac{1}{4}c_{3k}^\dagger c_{4l}c_{2j}^\dagger c_{1i}\lambda_{kl}^\alpha\lambda_{ji}^\beta\right) \left(-\frac{\alpha_s^2}{q^2}\right) [\bar{u}(3)\gamma^\mu u(1)] [\bar{v}(2)\gamma^\nu v(4)] \]

(2.2)

Similarly for t-channel we have,

\[-iM = \bar{u}(3)c_{3k}^\dagger\left(-i\frac{\alpha_s}{2}\bar{c}_{kl}\gamma^\mu\right) [c_{1i}u(1)] \left(-i\frac{g_{\mu\nu}\gamma^\rho}{q^2} \right) [\bar{v}(2)c_{2j}^\dagger]\left(-i\frac{\alpha_s}{2}\lambda_{ji}^\beta\gamma^\nu\right) [c_{4l}v(4)] \]

(2.3)
\[
M = \left( \frac{1}{4} c_3^\dagger c_4 c_2^\dagger c_1 \zeta_{kl} \zeta_{ji} \right) \left( \frac{-\alpha_s^2}{q^2} \right) \left[ \bar{u}(3) \gamma^\mu u(1) \right] \left[ \bar{v}(2) \gamma^\nu v(4) \right] (2\pi)^4 \delta^4(p_1 + p_2 - p_4 - p_4) \quad (2.4)
\]

The color factors for \( t^- \) and \( s^- \) channels are,

\[
f_t = \left( \frac{1}{4} c_3^\dagger c_4 c_2^\dagger c_1 \zeta_{kl} \zeta_{ji} \right) \quad f_s = \left( \frac{1}{4} c_3^\dagger c_4 c_2^\dagger c_1 \zeta_{kl} \zeta_{ji} \right) \quad (2.5)
\]

Since mesons are colorless they are in color singlet state given by,

\[
|\text{Meson}\rangle = \frac{1}{\sqrt{3}} (r\bar{r} + b\bar{b} + g\bar{g}) \quad (2.6)
\]

therefore,

\[
c_3^\dagger c_4 c_2^\dagger c_1 = \frac{1}{3} \delta_{ij} \delta_{kl} \quad (2.7)
\]

Now for \( s^- \) channel this condition results in,

\[
f_s = \frac{1}{12} \sum_{i,j,k,l=1}^3 \sum_{a=1}^8 \delta_{ij} \delta_{kl} \zeta_{a} = \frac{1}{12} \sum_{a=1}^8 Tr[A^a] Tr[A^a] = 0 \quad (2.8)
\]

which says that gluon, as a color octet, do not couple to a meson in color singlet state, this leaves us the \( t^- \) channel for which the color factor is given as,

\[
f_t = \frac{1}{12} \sum_{i,j,k,l=1}^3 \sum_{a=1}^8 \delta_{ij} \delta_{kl} \zeta_{a} = \frac{1}{12} \sum_{a=1}^8 Tr[A^a] = \frac{4}{3} \quad (2.9)
\]

Therefore we may conclude that one gluon exchange results in interaction with a Coulomb potential, \( V_{\bar{q}q}(r) \), given as,

\[
V_{\bar{q}q}(r) = -\frac{4 \alpha_s}{3} \frac{\alpha_s}{r} \quad (2.10)
\]

### 2.2 Breit Interaction

In the previous section simplification of one gluon exchange to an interaction via Coulomb potential was enough for showing the attractive nature of the interaction for color singlet states. However a rightful objection can be made that this is an oversimplification because it disregards all the relativistic nature of our problem. In this section we discuss how to include relativistic effects. Naturally when one deals with relativistic bound states, Bethe-Salpeter equation should be used. But for our problem at hand the high masses of charm and beauty quarks allow us to assume that our system can be approximated to be non relativistic. As a
first step in doing a non relativistic reduction, following Breit [9] we attempt to find a non-covariant expression for the scattering amplitude in the form,

\[ M_{NR} = \int \int \Psi^\dagger(p_3, E_3, j_3; 1) \Psi^\dagger(p_4, E_4, j_4; 2) \left( \frac{e^2}{r_{12}} + H_B(1, 2) \right) \]  \hspace{1cm} (2.11)

\times \Psi(p_2, E_2, j_2; 2) \Psi(p_1, E_1, j_1; 1) d^3r_1 d^3r_2

where

\[ \Psi(p_i, E_i, j_i; n) = e^{ip_i \cdot r_i / \hbar - iE_i t / \hbar} u(n) \]  \hspace{1cm} (2.12)

and \( H_B(1, 2) \) is the term that includes the relativistic correction. Finding \( H_B(1, 2) \) will benefit us in two ways, first it will enable us to find the relativistic correction to the first order and second, by evaluating its expectation value using the wavefunctions that we calculate for \( c\bar{c} \) and \( b\bar{b} \) mesons will give us an estimation of relativistic effects for our model.

Disregarding the color factor we rewrite the amplitude for one gluon exchange as

\[ M = \frac{1}{(E_1 - E_3)^2 - (p_1 - p_3)^2} \left[ \bar{u}(3) \gamma^\mu u(1) \right] \left[ \bar{v}(2) \gamma^\nu v(4) \right] \]  \hspace{1cm} (2.13)

\times (2\pi)^4 \delta(E_1 + E_2 - E_4 - E_4) \delta^3(p_1 + p_2 - p_4 - p_4)

In terms of \( \alpha_1, \beta_1 \) and \( \alpha_2, \beta_2 \) we can rewrite the the product of the fermion currents as

\[ \left[ \bar{u}(3) \gamma^\mu u(1) \right] \left[ \bar{v}(2) \gamma^\nu v(4) \right] = \left[ \bar{u}^\dagger(3) \gamma^0 \gamma^\mu u(1) \right] \left[ \bar{v}^\dagger(2) \gamma^0 \gamma^\nu v(4) \right] \]  \hspace{1cm} (2.14)

where \( \alpha_1 \) acts on the spinor space of the first particle and \( \alpha_2 \) to that of the second and they commute, so that

\[ M = \frac{1}{(E_1 - E_3)^2 - (p_1 - p_3)^2} \left[ \bar{u}^\dagger(3) \bar{v}^\dagger(2) (1 - \alpha_1 \cdot \alpha_2) u(1) v(4) \right] \]  \hspace{1cm} (2.15)

\times (2\pi)^4 \delta(E_1 + E_2 - E_4 - E_4) \delta^3(p_1 + p_2 - p_4 - p_4)
Or as an integration over space and time

\[
M = \int \int \int e^{i\mathbf{p}_1 \cdot \mathbf{r}_1 / \hbar} u(i) e^{-i\mathbf{p}_2 \cdot \mathbf{r}_2 / \hbar}(2) \left( \frac{1}{r_{12}} (1 - \alpha \cdot \alpha_1) e^{-|E_1 - E_2|r_{12}/\hbar} \right)
\]

(2.16)

Now using

\[
e^{-i\mathcal{L}E_1} u(n) = \Psi_{\alpha}(\mathbf{p}, E_{\alpha}, j_1) \]  

(2.17)

\[
e^{i\mathcal{L}E_2} v(n) = \Psi_{\alpha}(-\mathbf{p}, -E_{\alpha}, j_2; n) \]  

(2.18)

We obtain

\[
M_R = \int \int \int \Psi_{\alpha}(\mathbf{p}_3, E_3) \Psi_{\alpha}(-\mathbf{p}_2, E_2) \left\{ \frac{1}{r_{12}} (1 - \alpha \cdot \alpha_1) e^{-|E_1 - E_3|r_{12}/\hbar} \right\} x \Psi(\mathbf{p}_1, E_1) \Psi(-\mathbf{p}_4, -E_4) d^3r_1 d^3r_2
\]

(2.19)

To obtain the non-relativistic reduction of the amplitude \(M_R\) which we assume is of the form \(M_{NR}\) given in Eqn.[2.11], we observe that for one gluon exchange we are at short distances which are characterized by high momentum exchange \(|\mathbf{p}_1 - \mathbf{p}_3|\), quantitatively we may associate the distance between \(q\bar{q}\) pair to de Broglie wavelength [13],

\[
r_{12} \approx \hbar / |\mathbf{p}_1 - \mathbf{p}_3| \]  

(2.20)

Therefore the exponential in Eqn.[2.19] is at the order

\[
e^{-|E_1 - E_3|r_{12}/\hbar} = e^{-|E_1 - E_3|(|\mathbf{p}_1 - \mathbf{p}_3|} \]  

(2.21)

For the system we are concerned with the quark masses are at the order of GeV, therefore the exponent can be approximated as, \(|E_1 - E_3|/|\mathbf{p}_1 - \mathbf{p}_3| \approx (p_1 - p_3^2)/m^2c^2|\mathbf{p}_1 - \mathbf{p}_3| \ll 1.|.\)Where we have used \(E = \sqrt{p^2 + m^2} \approx m + p^2/2m\), since we assume quark masses to be high. Using this assumption we expand the term in the curly brackets in Eqn.[2.19],

\[
\frac{1}{r_{12}} (1 - \alpha_1 \cdot \alpha_1) e^{-|E_1 - E_2|r_{12}/\hbar} = \frac{1}{r_{12}} (1 - \alpha_1 \cdot \alpha_2)
\]

(2.22)

\[
\times \left( 1 + i \frac{|E_3 - E_1|r_{12}}{\hbar} - \frac{|E_3 - E_1|^2 r_{12}^2}{(\hbar)^2} + \ldots \right)
\]

\[
= \frac{1}{r_{12}} \frac{\alpha_1 \cdot \alpha_2}{r_{12}} + i \frac{|E_3 - E_1|r_{12}}{\hbar} - \frac{|E_3 - E_1|^2 r_{12}^2}{2(\hbar)^2} + \ldots \]  

(2.23)
The first term is just the Coulomb potential, the second term
\[ H_{B,m} = -\frac{\alpha_1 \cdot \alpha_2}{r_{12}} \] (2.24)
is called the Breit magnetic term and its physical meaning is explained below. The third term, \( |E_3 - E_1| \), does not have any dependence on \( r_{12} \) therefore for this term the integrals over \( r_1 \) and \( r_2 \) can be carried out separately to give zero, since the incoming and outgoing waves are considered to be orthogonal.

To find the contribution from the fourth term first we note that, since \((E_3 - E_1) = (E_2 - E_4)\),
\[ -\frac{|E_3 - E_1|^2 r_{12}}{2(ch)^2} = -\frac{(E_3 - E_1)(E_2 - E_4) r_{12}}{2(ch)^2} \]
(2.25)
\[ = -(E_3 E_2 + E_1 E_4 - E_1 E_2 - E_3 E_4) \frac{r_{12}}{2(ch)^2} \] (2.26)

Therefore the contribution is
\[ M_{Bre} = -\frac{1}{2} \int \int \int \Psi^\dagger(p_3, E_3) \Psi^\dagger(-p_2, -E_2) \]
\[ \times \left\{ \frac{r_{12}}{(ch)^2}(E_3 E_2 + E_1 E_4 - E_1 E_2 - E_3 E_4) \right\} \]
\[ \times \Psi(p_1, E_1) \Psi(-p_4, -E_4) d^3r_1 d^3r_2 dt \] (2.29)

To extract the Hamiltonian we need to replace energies with their operator form. Using
\[(ich\alpha_1 \cdot \nabla_i + \beta_im)\Psi_n(p_n, E_n) = E_n\Psi_n(p_n, E_n)\] (2.30)
where \(i = 1(2)\) for \(n = 1, 3, (2, 4)\), we express the product of energies as
\[ \Psi^\dagger(p_3, E_3) \Psi^\dagger(-p_2, -E_2) \frac{r_{12}}{(ch)^2}(E_3 E_2) = \Psi^\dagger(p_3, E_3) \Psi^\dagger(-p_2, -E_2)(-ich\alpha_1 \cdot \nabla_1 + \beta_1m) \]
(2.31)
\[ \times (-ich\alpha_2 \cdot \nabla_2 + \beta_2m) \frac{r_{12}}{(ch)^2} \]
\[ \frac{r_{12}}{(ch)^2}(E_1 E_4) \Psi(p_1, E_1) \Psi(-p_4, -E_4) = \frac{r_{12}}{(ch)^2}(ich\alpha_1 \cdot \nabla_1 + \beta_1m)(ich\alpha_2 \cdot \nabla_2 + \beta_2m) \]
\[ \times \Psi(p_1, E_1) \Psi(-p_4, -E_4) \] (2.32)
\[ -\Psi^\dagger(-p_2, -E_2) \Psi(p_1, E_1) \frac{r_{12}}{(ch)^2}(E_1 E_2) = -\Psi^\dagger(-p_2, -E_2)(-ich\alpha_2 \cdot \nabla_2 + \beta_2m) \frac{r_{12}}{(ch)^2} \]
\[ \times (ich\alpha_1 \cdot \nabla_1 + \beta_1m) \Psi(p_1, E_1) \] (2.33)
\[ -\Psi^\dagger(-p_3, -E_3) \Psi(p_4, E_4) \frac{r_{12}}{(ch)^2}(E_3 E_4) = -\Psi^\dagger(-p_3, -E_3)(-ich\alpha_1 \cdot \nabla_1 + \beta_1m) \frac{r_{12}}{(ch)^2} \]
\[ \times (ich\alpha_2 \cdot \nabla_2 + \beta_2m) \Psi(p_4, E_4) \] (2.34)
Observing that, since $\beta_1, \beta_2$ commute with $r_{12}$, the terms with $\beta_1 \beta_2 r_{12}$ and $\beta \alpha \cdot \nabla$ cancel out, resulting in,

$$M_{B, ret} = -\frac{1}{2} \int \int \int \psi^\dagger(p_3, E_3) \psi^\dagger(-p_2, -E_2) \times \{-\alpha_1 \cdot \nabla_1 \alpha_2 \cdot \nabla_2 r_{12} - r_{12} \alpha_1 \cdot \nabla_1 \alpha_2 \cdot \nabla_2 + \alpha_1 \cdot \nabla_1 \alpha_2 \cdot \nabla_2 + \alpha_2 \cdot \nabla_2 r_{12} \alpha_1 \cdot \nabla_1 \} \times \psi(p_1, E_1) \psi(-p_4, -E_4) d^3 r_1 d^3 r_2 dt$$

(2.35)

The term in the curly brackets can be evaluated using,

$$-\alpha_1 \cdot \nabla_1 \alpha_2 \cdot \nabla_2 r_{12} = -\alpha_1 \cdot \nabla_1 (\alpha_2 \cdot r_{12} \nabla_2 + \nabla_2 r_{12})$$

$$= -r_{12} \alpha_1 \cdot \nabla_1 \alpha_2 \cdot \nabla_2 - \alpha_1 \cdot \nabla_1 (\alpha_2 \cdot \nabla_2) + \alpha_2 \cdot \nabla_2 (\alpha_2 \cdot r_{12}) - \alpha_2 \cdot \nabla_2 (r_{12}) \alpha_1 \cdot \nabla_1$$

(2.36)

$$\alpha_1 \cdot \nabla_1 r_{12} \alpha_2 \cdot \nabla_2 = r_{12} \alpha_1 \cdot \nabla_1 \alpha_2 \cdot \nabla_2 + \alpha_1 \cdot \nabla_1 (\alpha_2 \cdot \nabla_2)$$

(2.37)

$$\alpha_2 \cdot \nabla_2 r_{12} \alpha_1 \cdot \nabla_1 = r_{12} \alpha_2 \cdot \nabla_2 \alpha_1 \cdot \nabla_1 + \alpha_2 \cdot \nabla_2 (\alpha_1 \cdot \nabla_1)$$

(2.38)

Putting everything together we obtain,

$$M_{B, ret} = -\frac{1}{2} \int \int \int \psi^\dagger(p_3, E_3) \psi^\dagger(-p_2, -E_2) \times \psi(p_1, E_1) \psi(-p_4, -E_4) d^3 r_1 d^3 r_2 dt$$

(2.39)

(2.40)

Allowing us the to identify the operator responsible for the retardation effect,

$$H_{B, ret} = -\frac{1}{2} (\alpha_1 \cdot \nabla_1) (\alpha_2 \cdot \nabla_2) (r_{12})$$

(2.41)

Which together with 2.24, gives the Breit operator,

$$H_{Breit} = -\frac{\alpha_1 \cdot \alpha_2}{r_{12}} + \frac{1}{2} (\alpha_1 \cdot \nabla_1) (\alpha_2 \cdot \nabla_2) (r_{12})$$

(2.42)

Or,
\[ H_{\text{Breit}} = -\frac{1}{2} \left[ \frac{\alpha_1 \cdot \alpha_2}{r_{12}} + \frac{(\alpha_1 \cdot \mathbf{r}_{12})(\alpha_2 \cdot \mathbf{r}_{12})}{r_{12}^3} \right] \]  

(2.43)

Therefore if one considers the lowest order relativistic corrections to one-gluon exchange, the relativistic Hamiltonian for the quark-anti-quark system may be given as,

\[ H = c\alpha_1 \cdot p_1 + c\alpha_2 \cdot p_2 + \beta_1 mc^2 + \beta_2 mc^2 - \frac{1}{r_{12}} - \frac{1}{2} \left[ \frac{\alpha_1 \cdot \alpha_2}{r_{12}} + \frac{(\alpha_1 \cdot \mathbf{r}_{12})(\alpha_2 \cdot \mathbf{r}_{12})}{r_{12}^3} \right] \]  

(2.44)

### 2.3 Potential Model

#### 2.3.1 The Cornell Potential

As mentioned before Quark Model needs to embrace both the non-perturbative and perturbative regimes of QCD. As shown in the previous section, in perturbative regime, where coupling is small we only need to consider one gluon exchange which, ignoring the color factor, is just a Coulomb potential for color singlet states,

\[ V_{1g}(r) = -\frac{4}{3} \frac{\alpha_s}{r} \]  

(2.45)

To account for the non-perturbative regime, different potential models have been proposed in the early days of the quark model, most notable ones are the logarithmic potential \( \ln(r) \) and power-law potential, \( r^n \)[37]. Today, with the results from Lattice QCD, Wilson Loop Calculations and Effective Field Theory approach we expect that confining potential should be linear,

\[ V_{\text{Conf}}(r) = \sigma r \]  

(2.46)

The resulting phenomenological potential together with constant term \( V_0 \),

\[ V_{\text{Cornell}} = -\frac{4}{3} \frac{\alpha_s}{r} + \sigma r + V_0 \]  

(2.47)
is called the Cornell potential, where $V_0$ is a constant. Although at first sight adding a constant term may seem illegal, we note that there is no counter argument for such a term, and there is no harm in including it except increasing parameters.

### 2.3.2 Breit-Fermi Interactions

Cornell potential on its own is unfortunately unable to explain spin splittings, such as $J/\Psi$ and $\eta_c$, and $P$ wave splittings such as $\chi_{c0}, \chi_{c1}, \chi_{c2}, h_c$. To include these splittings we have to include spin-dependent terms to the potential.

As it is clear now we face two different energy regimes and we have no clue from the theory about how the spin dependent dependent forces change with the distance. As shown in [14] hypothesizing that the spin-dependent forces are attributed to the short distance potential, one can explain the observed Hadron masses to a high precision. Also from [17], [18] and[44] Cornell potentials success in building a model for Charmonium can be observed.

In this section we show how to obtain the the spin dependent potentials following the assumption that it results from the 1-gluon exchange. In the previous section we have already found a non-covariant Dirac Hamiltonian which included retardation effects. As it is a relativistic Hamiltonian it is spin dependent and it mixes negative and positive energy solutions. To use this Hamiltonian in our non-relativistic model we can remove such a mixing by making a non relativistic reduction which in turn will allow us to separate spin and space parts of the wavefunction, providing us with spin dependent forces occurring at higher orders of $1/m$.

Such a non-relativistic reduction is made in Appendix A, by using generalized Foldy-Wouthuysen transformation for two particles. The result of non-relativistic expansion to order $1/m^3$ is given as,
\[ H_{BF} = -\frac{4}{3} \frac{\alpha_s}{r} \]

\[ + 2m_q + \frac{p^2}{m_q} - \frac{p^4}{4m_q^3} \]  

\[ - \frac{2}{3} \frac{\alpha_s}{m_q^2} \left( \frac{p^2}{r} + \frac{r(r \cdot p) \cdot p}{r^3} \right) \]

\[ + \frac{4}{3} \frac{\alpha_s}{m_q^2} \delta(r) \left( 1 + \frac{8\pi}{3} S_1 \cdot S_2 \right) \]

\[ + 2 \frac{\alpha_s}{m_q^2 r^3} ((S_1 + S_2) \cdot L) \]

\[ + 4 \frac{\alpha_s}{3 m_q^2 r^2} \left( \frac{3(S_1 \cdot r)(S_2 \cdot r)}{r^2} - S_1 \cdot S_2 \right) \]

We know put the Breit interaction, term by term in a form suitable for our method of using the radial solutions of the Harmonic Oscillator and give the explanation of each term.

### 2.3.2.1 Increase of Relativistic Mass

Eqn [2.49] corresponds the expansion of \( 2 \sqrt{p^2 + m_q^2} \).

\[ V_{rm} = 2m + \frac{p^2}{m} - \frac{p^4}{4m^3} \]  

(2.54)

Such a term arises when one considers the relativistic mass, \( \gamma m_0 \) instead of the rest mass \( m_0 \).

In our model we are only interested in terms contributing to the the order \( m^2 \) therefore we discard the term \(-\frac{p^4}{4m^3}\) and use

\[ 2m_q + \frac{p^2}{m_q} \]  

(2.55)

instead, which corresponds to the Schrodinger Hamiltonian without a potential.

### 2.3.2.2 Retardation of Potential

Eqn (2.50), as explained in detail in the previous section arises from the retardation of the potential resulting from the finite speed of propagation of light (gluons in our case). In operator
form it is given as

$$\langle \Psi_{nlm}(r) \mid V_{ret} \mid \Psi_{n'l'm'}(r) \rangle = \left\{ -\frac{2}{3} \frac{\alpha_s}{m_q^2} \int r^2 dr R_n \left( \frac{\nabla^2}{r} + \frac{1}{r \frac{\partial^2}{\partial r^2}} \right) R_{n'} \int d\Omega Y_{lm}^* Y_{l'm'} \right. $$

$$+ \int r^2 dr R_n R_{n'} \int d\Omega Y_{l'm'}^* Y_{lm} \right\}$$

$$= \frac{2}{3} \frac{\alpha_s}{m_q^2} \int dr \left\{ -\frac{2}{r^2} u_{n'} u_n'' - \frac{2}{r^2} u_{n'} u_n' + 2 - l(l+1) \frac{r^3}{m_q^2} u_{n'} \right\} \delta_{nn'} \delta_{ll'}$$

$$= \frac{2}{3} \frac{\alpha_s}{m_q^2} \int dr \left\{ -\frac{2}{r^2} u_{n'} u_n'' - \frac{2}{r^2} u_{n'} u_n' + 2 - l(l+1) \frac{r^3}{m_q^2} u_{n'} \right\} \delta_{nn'} \delta_{ll'}$$

$$\tag{2.56}$$

Note that we use the radial solutions of the harmonic oscillator but the above term also acts on the angular part. We separate the angular dependency as follows,

$$\langle \Psi_{nlm}(r) \mid V_{ret} \mid \Psi_{n'l'm'}(r) \rangle = \left\{ -\frac{2}{3} \frac{\alpha_s}{m_q^2} \int r^2 dr R_n \left( \frac{\nabla^2}{r} + \frac{1}{r \frac{\partial^2}{\partial r^2}} \right) R_{n'} \int d\Omega Y_{lm}^* Y_{l'm'} \right. $$

$$+ \int r^2 dr R_n R_{n'} \int d\Omega Y_{l'm'}^* Y_{lm} \right\}$$

$$= \frac{2}{3} \frac{\alpha_s}{m_q^2} \int dr \left\{ -\frac{2}{r^2} u_{n'} u_n'' - \frac{2}{r^2} u_{n'} u_n' + 2 - l(l+1) \frac{r^3}{m_q^2} u_{n'} \right\} \delta_{nn'} \delta_{ll'}$$

$$= \frac{2}{3} \frac{\alpha_s}{m_q^2} \int dr \left\{ -\frac{2}{r^2} u_{n'} u_n'' - \frac{2}{r^2} u_{n'} u_n' + 2 - l(l+1) \frac{r^3}{m_q^2} u_{n'} \right\} \delta_{nn'} \delta_{ll'}$$

$$\tag{2.57}$$

2.3.2.3 Darwin Term

The first term in Eq.(2.51),

$$V_{Darwin} = \frac{4}{3} \frac{\alpha_s}{m_q^2} \delta(r)$$

is called the Darwin term and may be attributed zitterbewegung [5]. It is a correction that includes the smearing out of the potential caused by the fluctuation of the particle, quark and anti-quark in this case, over the distance $\delta r \approx 1/m_q$. The smearing may be approximated as,

$$\langle \delta V \rangle = \langle V(r + \delta r) \rangle - \langle V(r) \rangle = \langle \frac{\partial V}{\partial r} \delta r + \delta r_i \delta r_j \frac{\partial^2 V}{\partial r_i \partial r_j} \rangle \approx \frac{1}{6} \delta r^2 \nabla^2 V \approx \frac{1}{\delta m^2} \nabla^2 V$$

$$\tag{2.59}$$

To include this term in our Hamiltonian, we write Dirac Delta function in spherical coordinates,

$$V_{Darwin} = \frac{4}{3} \frac{\alpha_s}{m_q^2} \delta(r) = \frac{4}{3} \frac{\alpha_s}{m_q^2} \frac{\delta(r)}{2\pi r^2}$$

$$\tag{2.60}$$
by noting that \( 1 = \int dr r^2 R_{nl}(r) \int d\Omega Y_{lm}(\theta, \phi) = (4\pi) \int dr r^2 R_{nl}(r) \) and that the integration is from \(0^+\) to \(\infty\). Obviously this term only contributes only for \(l = 0\) states for which there is no centrifugal potential, and radial wavefunction \(R_{nl}\) is non-zero at the origin.

### 2.3.2.4 Spin-Spin Interaction

The spin-spin interaction term,

\[
\frac{4}{3} \frac{\alpha_s}{m_q^2} \delta(r) \left( \frac{8\pi}{3} \mathbf{S}_1 \cdot \mathbf{S}_2 \right)
\]

arises when one considers two particles. Together with the regular Spin-Spin interaction its presence is vital in explaining the \(S\) wave splittings. Note that it has no effect for \(l \neq 0\) states. In \(|j, l, s, m_j\rangle\) basis it is given as

\[
V_{SS,\text{con}} = \frac{16}{9} \frac{\alpha_s}{m_q^2} \frac{\delta(r)}{r^2} \left( S(S + 1) - \frac{3}{2} \right)
\]

where we have used \(\mathbf{S}_1 \cdot \mathbf{S}_2 = \frac{1}{2}(S^2 - S_1^2 - S_2^2) = \frac{1}{2}(S(S + 1) - \frac{3}{2})\).

### 2.3.2.5 Spin-Orbit Coupling

The spin-orbit coupling term is responsible for \(P\) wave splittings and given as,

\[
V_{SO}(r) = 2 \frac{\alpha_s}{m_q^2 r^3} (3(\mathbf{S}_1 + \mathbf{S}_2) \cdot \mathbf{L})
\]

\[
= \frac{\alpha_s}{m_q^2 r^3} (J(J + 1) - L(L + 1) - S(S + 1))
\]

where we have used

\[
\mathbf{L} \cdot \mathbf{S} = \frac{1}{2} \left( (\mathbf{L} + \mathbf{S})^2 - \mathbf{L}^2 - \mathbf{S}^2 \right)
\]

\[
= \frac{1}{2} \left( \mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2 \right)
\]

\[
= \frac{1}{2} \left( J(J + 1) - L(L + 1) - S(S + 1) \right)
\]
2.3.2.6 Tensor Force

The tensor potential is given as

\[
V_{\text{Tensor}} = \frac{4}{3} \frac{\alpha_s}{m_Q^2 r^3} \left( 3 \frac{(S_1 \cdot r)(S_2 \cdot r)}{r^2} - S_1 \cdot S_2 \right) \tag{2.65}
\]

It is vital in explaining the non-uniformity of the splittings between \(L = 1, S = 1\) states such as \( \chi_{c2}, \chi_{c1} \) and \( \chi_{c0} \). In \( |j, l, s, m_j\rangle \) basis its given as (see Appendix B for Derivation),

\[
T_{\text{Tensor}} = 3 \frac{(\vec{S}_i \cdot r)(\vec{S}_j \cdot r)}{r^2} - \vec{S}_i \cdot \vec{S}_j = \begin{cases} 
-\frac{l}{2(2l+3)} & j = l + 1 \\
1/2 & j = l \\
-\frac{(j+1)}{2(2l-3)} & j = l - 1 \\
0 & l = 0 \text{ or } s = 0
\end{cases} \tag{2.66}
\]

where

\[
V_{\text{Tensor}}(r, j, l, s) = \frac{4}{3} \frac{\alpha_s}{m_Q^2} T_{\text{Tensor}}(j, l, s) \tag{2.67}
\]
CHAPTER 3

METHOD

3.1 Schrödinger Equation with Central Potential

The fundamental assumption of the quark model is that the constituent quarks obey the non-relativistic Schrödinger equation. Under this assumption we find the non-relativistic reduction of the Breit Hamiltonian using a Foldy Wouthuysen transformation (details are in Appendix A). This reduction allows us to separate the spin and space parts of the meson wavefunction where space part of the wavefunction satisfies the Schrödinger equation with spin dependent potential.

To analyze the motion we start with the Hamiltonian for two particles interacting through an isotropic potential and separate the motion of center of mass,

$$H = \frac{p_1^2}{2} + \frac{p_2^2}{2} + V_0(|r_1 - r_2|) = \frac{p^2}{2(m_1 + m_2)} + \frac{\mu}{2} + V_0(|\vec{r}|) = H_{CM} + H_{rel} \tag{3.1}$$

where

$$P = p_1 + p_2, \quad \mu = \frac{m_1 m_2}{m_1 + m_2}$$

$$r = r_1 + r_2$$

$$H_{CM} = \frac{p^2}{2(m_1 + m_2)}, \quad H_{rel} = \frac{\mu}{2}$$

Substituting $\vec{p} \rightarrow -i\vec{\nabla}$ in the Hamiltonian for the relative motion we find the Schrödinger equation,

$$\left[-\frac{\nabla^2}{2\mu} + V_0(r)\Psi(r)\right] = E\Psi(r) \tag{3.2}$$

Next we separate the wavefunction into radial and angular parts,

$$\Psi(\vec{r}) = R(r)Y_{lm}(\theta, \phi) \tag{3.3}$$
Radial part satisfies
\[
\left[ -\frac{1}{2\mu} \frac{\partial^2}{\partial r^2} + \frac{2}{r} \frac{\partial}{\partial r} + \frac{l(l + 1)}{2\mu r^2} + V_0(r) \right] R_{kl}(r) = E_{kl} R_{kl}(r) \quad (3.4)
\]
whereas the angular wavefunctions given in terms of spherical harmonics,
\[
Y_{lm}(\theta, \phi) = \epsilon \sqrt{\frac{(2l + 1)(l - |m|)!}{4\pi (l + |m|)!}} e^{im\phi} P_l^m(\cos \theta) \quad (3.5)
\]
where \(\epsilon = (-1)^m\) for \(m \geq 0\) and \(\epsilon = 1\) for \(m \leq 0\).

Defining \(u_{kl}(r) = r R_{kl}(r)\), the radial equation simplifies to the 1 dimensional case with effective potential,
\[
\left[ -\frac{1}{2\mu} \frac{\partial^2}{\partial r^2} + \frac{l(l + 1)}{2\mu r^2} + V_0(r) \right] u_{kl}(r) = E_{kl} u_{kl}(r) \quad (3.6)
\]
The normalization conditions are given as,
\[
\int drr^2 [R_{kl}(r)]^2 = \int dr [u_{kl}(r)]^2 = 1 \quad (3.7)
\]
\[
\int d\Omega |Y_{lm}(\theta, \phi)|^2 = 1 \quad (3.8)
\]

### 3.1.1 Simple Harmonic Oscillator in Three Dimensions

We will use the radial solutions of isotropic simple harmonic oscillator in three dimensions as our base space to diagonalize the Hamiltonian. The radial part of the 3D SHO wavefunction satisfies,
\[
\left( -\frac{1}{2\mu} \nabla^2 + \frac{\gamma^2}{\mu} r^2 - E_n \right) R_{SHO,nl} = 0 \quad (3.9)
\]
and the radial equation is given as,
\[
R_{SHO,nl}(r, \nu) = N_{nl} r^l e^{-\nu r^2} L_{\frac{n-l}{2}}^{(l+\frac{1}{2})}(2\nu r^2) \quad (3.10)
\]
where \(\mu\) is the reduced mass and,
\[
N_{nl} = \sqrt{\frac{2\nu^3}{\pi} \frac{2(n-l)!!}{(n+\frac{l}{2})!!}} \quad (3.11)
\]
ensures normalization. \(L_{\frac{n-l}{2}}^{(l+\frac{1}{2})}(2\nu r^2)\) are generalized Laguerre polynomials. The quantum number \(n\) denotes the energy values.
\[
E_{3D\text{SHO}} = \hbar \omega \left( n + \frac{3}{2} \right) \quad (3.12)
\]
\( l \) denotes the total angular momentum. \( \frac{n-l}{2} = k \) gives the radial quantum number and is an integer. Therefore \( n \) can have the values

\[
n = 0, 1, 2, ...
\]

and \( l \) can have,

\[
l = \begin{cases} 
  0, 2, 4, ..., n & \text{for } n \text{ even} \\
  1, 2, 3, ..., n & \text{for } n \text{ odd}
\end{cases}
\]

\( \nu \) is the parameter of wave function depending on the angular frequency of the harmonic oscillator. We will fix this parameter by considering a perturbation,

\[
\delta V = kx - \mu \omega^2 r^2
\] (3.13)

to the Hamiltonian given in 3.9. The first order correction to the ground state is given as,

\[
\langle u_{\text{SHO},0} \vert \delta V \vert u_{\text{SHO},0} \rangle = \frac{4k}{3} \sqrt{\frac{2}{\pi}} - \frac{5m\omega^2}{8\nu}
\] (3.14)

Now we demand this perturbation to vanish, obtaining

\[
\nu_0 = \frac{4k^{2/3} \mu^{2/3}}{15^{2/3} \pi^{1/3}}
\] (3.15)

At this stage the basis vectors are given by,

\[
u_{\text{SHO},n} \equiv rR_{\text{SHO},nl}(r, \nu_0) = N_{nl} r^{l+1} e^{-\nu r^2} L_{\frac{l+1}{2}}^{(l+\frac{1}{2})}(2\nu r^2)
\] (3.16)

### 3.1.2 Method

To summarize we use the 3D SHO reduced radial wavefunctions,

\[
u_{\text{SHO},nl}(r, \nu) = N_{nl} r^{l+1} e^{-\nu r^2} L_{\frac{l+1}{2}}^{(l+\frac{1}{2})}(2\nu r^2)
\] (3.17)
to diagonalize the Hamiltonian given as

\[
H = -\frac{1}{m_q} \frac{\partial^2}{\partial^2 r} + \frac{l(l + 1)}{m_q r^2} + \frac{4}{3} \frac{\alpha_s}{m_q} + \sigma r + 2m_q + \frac{p^2}{m_q} - \frac{2}{3} \frac{\alpha_s}{m_q^2} \left( \nabla^2 \frac{1}{r} + \frac{1}{r \partial r} \right) + \frac{4}{3} \frac{\alpha_s}{m_q^2} \frac{\delta(r)}{2\pi r^2} \left( 1 + \frac{4\pi \delta(r)}{3} \left( S(S + 1) - \frac{3}{2} \right) \right) + \frac{\alpha_s}{m_q^2} r (J(J + 1) - L(L + 1) - S(S + 1)) + \frac{4}{3} \frac{\alpha_s}{m_q^2} r^3 T_{\text{tensor}}(j, l, s)
\] (3.18)

Obtaining,

\[
Hu_{\bar{q}q,k,j,l,s}(r) = E_{n,j,l,s} u_{\bar{q}q,k,j,l,s}(r)
\] (3.19)

where \(u_{\bar{q}q,k,j,l,s}(r)\) is the reduced radial wavefunction of the meson, i.e.,

\[
u_{\bar{q}q,k,j,l,s}(r) \equiv r R_{\bar{q}q,k,j,l,s}(r)
\] (3.20)

and is given by in terms of 3D SHO reduced wavefunctions as,

\[
u_{\bar{q}q,k,j,l,s}(r) = \begin{cases} 
\sum_{n=0}^{2D-2} c_n u_{\text{SHO},n,l} & \text{for } l = \text{even} \\
\sum_{n=0}^{l+2D-2} c_n u_{\text{SHO},n,l} & \text{for } l = \text{odd}
\end{cases}
\] (3.21)

Where \(D\) is the number of the SHO wavefunctions forming the base space, i.e. the dimension of the Hamiltonian matrix that we diagonalize. And the mass of the meson is found by adding the two times the mass of quark to the eigenenergy,

\[
M_{k,j,l,s} = 2m_q + E_{k,j,l,s}
\] (3.22)

To find the fitting parameters, \((\alpha_s, k, m_q)\) we define,

\[
\chi^2(\alpha_s, k, m_q) = \sum \left( \frac{M_{\text{exp},k,j,l,s} - M_{k,j,l,s}}{\Delta M_{\text{exp},k,j,l,s}} \right)^2
\] (3.23)

Where \(M_{\text{exp},n,j,l,s}\) is the experimental observations of the meson masses and \(\Delta M_{\text{exp},n,j,l,s}\) is the error in measurements. Using Mathematica, the parameters \((\alpha_s, k, m_q)\) are fixed so that \(\chi^2\) is
a minimum. The dimension of the base space is chosen to be 30. Convergence is observed by considering base spaces with different dimensions.
4.1 Charmonium

Using the method described above we fit the parameters as

\[
\begin{align*}
\alpha_s & \quad \sigma & \quad m_c \\
0.3864 & \quad 0.2192\text{GeV}^2 & \quad 1.260\text{GeV}
\end{align*}
\]  

(4.1)

The predicted spectrum for Charmonium is given in Table 1. We also plot the ground state and first excited state wavefunctions. In [28] the mass of the charm quark is given between 1.18 GeV-1.34 GeV, and our mass value lies inside this range. Also the fitted \(\sigma\) is above the results obtained from lattice simulations which is around \(\sigma_{\text{lattice}} \approx 0.15\text{GeV}^2\)[30]. The value we obtained for \(\alpha_S\) is only half the value of that obtained for Charmonium from lattice calculations, which is around 0.65.

Comparing the found mass spectrum with the experimental results we see that our model for describing the 1S splitting is not as much as successful as we would like it to be, considering we only use 1S and 1P results for the fit.

For excited states we see that our calculations give increasingly higher mass. This might be attributed to the closeness of this state to \(D - \bar{D}\) threshold.
Figure 4.1: Charmonium Spectrum Showing Experimental Measurements(Black) vs. Fitted Mass Values (Blue, dotted).

### 4.2 Bottomonium

For the Bottomonium we fit the parameters as,

\[
\alpha_s \quad \sigma \quad m_b
\]

\[
0.3262 \quad 0.2902 \text{GeV} \quad 4.630
\]

The predicted spectrum is given in Table 2. We also plot the ground state and first excited state wavefunctions. In [28] the mass of the bottom quark is given between (4.49 – 4.61)GeV, our fitted mass is slightly above this range. \( \sigma \) is found to be above the lattice predictions \( \sigma_{\text{lattice}} \approx 0.15 \text{ GeV}^2 \). One expects the string tension to remain the same for different flavors but our model fails to predict this property, this may be attributed to the failure of the fit for Charmonium spectra. Compared to Charmonium a smaller value for \( \alpha_s \) is obtained. This is in agreement with the asymptotic freedom, since as we can observe from the graph the radial wavefunctions are packed closer to the origin, meaning a larger value for the momentum exchange therefore a smaller value for the \( \alpha_s \).

</table>

Compared to Charmonium we obtain a better fit for Bottomonium. Our models seems to do well in explaining both $1P$ and $2P$ splittings.

We note that our model predicts only slightly higher value for $\Upsilon(3S)$ and $\Upsilon(4S)$ states.
The success of our model for Bottomonium may be attributed to $b$ quarks high mass, which suits our non-relativistic approximation. Also we note that comparing the plots given for $1P$ Charmonium (Fig.3) and Bottomonium (Fig.6) states, Charmonium $1P$ states are split heavily by the spin-orbit coupling and the tensor force, while Bottomonium states show same regularity. This can be attributed to the fact that spin-orbit and tensor forces are proportional to the square of the inverse mass, $(\frac{1}{m_q})^2$. Therefore it may be concluded that to model Charmonium better we need to consider a relativistic model or include higher order relativistic corrections.

4.3 E1 and M1 Radiative Transitions

To calculate the partial widths of the E1 radiative transitions we use[19],

$$
\Gamma_{E1}(n^{2S+1}L_J \rightarrow n^{2S'+1}L'_J + \gamma) = \frac{4}{3} C_{fi} \delta_{SS'} e_q^2 \alpha \langle R_f | r | R_i \rangle^2 E_\gamma^3
$$

(4.3)

where, $e_q$ is the quark charge, $\alpha$ is the fine-structure constant and $E_\gamma$ is the final photon energy, given as $E_\gamma = (M_f - M_i)^2/2M_i$ in terms of the masses of the initial and final mesons. The matrix element $C_{fi}$ is given as,

$$
C_{fi} = \max(L, L')(2J' + 1) \left\{ \begin{array}{ccc} L' & J' & S \\ J & L & 1 \end{array} \right\}
$$

(4.4)
Figure 4.5: Bottomonium Spectrum Showing Experimental Measurements (Black) vs. Fitted Mass Values (Blue, dotted).

Figure 4.6: Squared reduced radial wavefunctions for $\eta_b$ (blue straight) and $\Upsilon(1S)$ (red dashed)
Figure 4.7: Squared radial wavefunctions for $\eta_b(2S)$ (blue straight) and $\Upsilon(2S)$ (red dashed)

Figure 4.8: Squared radial wavefunctions for $\chi_{b0}$ (blue straight), $\chi_{b1}$ (red dashed), $h_b$ (green dot-dashed) and $\chi_{b2}$ (black-thick)
To calculate the matrix elements, $| \langle R_f | r | R_i \rangle |$, where $R$ represents the radial wavefunction of the meson, we use the reduced radial wave functions calculated previously, therefore,

$$| \langle R_f | r | R_i \rangle | = \int_0^\infty r dr u_{q\bar{q},j_f,j_f,j_f,s_f} u_{q\bar{q},j_i,j_i,j_i,s_i}$$

(4.5)

For M1 transitions we use[19],

$$\Gamma_{M1}(n^{2S+1}L_J \rightarrow n'^{2S'+1}L'_{J'}, + \gamma) = \frac{4}{3} \frac{2J'}{2L + 1} \delta_{S,S'} \delta_{L,L'} \frac{e_q^2}{m_q^2} \alpha | \langle R_f | R_i \rangle |^2 E_\gamma^3$$

(4.6)

The results of the calculations are given in the Tables [4.2-4.9]. For the masses of the initial and final states we use the experimental values only if experimental value is available for both the initial and the final state, otherwise we use the calculated mass values given in the preceding section.

Comparing with the experimental data we conclude that our calculations are at the same order with the experimental results, therefore verifying that M1 rates to be highly suppressed. As mentioned in the preceding section, a relativistic model may give better results. Also we note that we observed a high dependence of the matrix elements on the parameters, further study is required to refine the method.

CHAPTER 5

CONCLUSION

In this work we investigate the Charmonium and Bottomonium spectra and radiative decays using the basic assumptions of the quark model.

We adopted the hypothesis that spin dependent potentials are attributable to the short distance part of the potential. For the short distance part, assuming that the perturbative approach works, we have derived the Coulomb interaction and a relativistic correction to the first order, the Breit Interaction. By making a non-relativistic reduction via Foldy-Wouthuysen transformation we extracted spin-dependent potential from one gluon exchange and explained the physical meaning of the various parts of the potential.

Furthermore we present our method of using 3D harmonic oscillator solutions to diagonalize the derived Hamiltonian therefore obtaining the masses and wavefunctions of $c\bar{c}$ and $b\bar{b}$ mesons. Using these wavefunctions we also calculate the partial widths of the radiative E1 and M1 decays.

Finally we present the results of our analysis for the spectrum of Charmonium and Bottomonium and the fitted values of the parameters, $m_c$, $m_b$, $\sigma$, $\alpha_s$. We also give plots of the radial wavefunctions for some Bottomonium and Charmonium states. For the $b\bar{b}$ the predicted mass values agree well with the experiments whereas for $c\bar{c}$, our model fails to predict the spectrum precisely. By comparing with the experimental and lattice results we comment on the shortcomings of our method.

All in all we believe that, this study was beneficial in investigating the fundamental assumptions of the Quark Model and setting up a crude model for the Charmonium and Bottomonium systems that can explain the fundamental properties of the spectrum. For a more detailed
analysis, a relativized approach together with a procedure to take $B\bar{B}$ and $D\bar{D}$ thresholds into account must be followed. In such a scheme consideration of light quarks would be possible.

APPENDIX A

FOLDY-WOUTHUYSEN TRANSFORMATION

We start with a Dirac Hamiltonian for two particles with an arbitrary potential, \( V \),
\[
H = \alpha^I \cdot p^I + \alpha^{II} \cdot p^{II} + \beta^I m_I + \beta^{II} m^{II} + V
\]  
(A.1)

The Dirac matrices are \( 16 \times 16 \) matrices, \( \alpha^I \) and \( \beta^I \) operate on the spinor space of the first particle and \( \alpha^{II} \) and \( \beta^{II} \) operate on those of the second particle, with elements given as,
\[
(\alpha^I)_{jk,JK} = (\alpha^I)_{jk}(\delta)_{JK}, \quad (\beta^I)_{jk,JK} = (\delta)_{jk}(\beta^I)_{JK}
\]  
(A.2)
\[
(\alpha^{II})_{jk,JK} = (\delta)_{jk}(\alpha^{II})_{JK}, \quad (\beta^{II})_{jk,JK} = (\delta)_{jk}(\beta^{II})_{JK}
\]  
(A.3)

Therefore the commutation relations are of the form,
\[
(a_{n^{(II)}}^{(II)})^2 = (\beta_{n^{(II)}}^{(II)})^2 = I_{16x16}
\]  
(A.4)
\[
[(\alpha^I)_{jk,JK},(\alpha^I)_{j',k',J'K'}]_+ = 2(\delta)_{kk'}(\delta)_{JJ'}(\delta)_{jj'}(\delta)_{KK'}
\]  
(A.5)

Note that the operator \( \alpha^{(II)} \cdot p^{(II)} \) mixes states with negative and positive energy of the \( 1^{st} \) (2\textsuperscript{nd}), which is the result of the relativistic nature of the Dirac equation. In order to obtain a non-relativistic equation we need to remove this mixing. We identify such operators by considering their commutation with \( \beta^I \) and \( \beta^{II} \). We label the operators as \( EE \) (even-even) if they commute with \( \beta^I \) and \( \beta^{II} \), \( OO \) if they anti-commute with both \( \beta^I \) and \( \beta^{II} \), and \( EO \)(\( OE \)) if they commute with \( \beta^I \)(\( \beta^{II} \)) and anti-commute with \( \beta^{II} \)(\( \beta^I \)), i.e,

\[
[OO,\beta^I]_+ = [OO,\beta^{II}]_+ = 0
\]  
(A.6)
\[
[EE,\beta^I]_+ = [EE,\beta^{II}] = 0
\]  
(A.7)
\[
[EO,\beta^{II}]_+ = [EO,\beta^I]_+ = 0
\]  
(A.8)
\[ [\mathcal{E} \mathcal{O}, \beta^I] = [\mathcal{O} \mathcal{E}, \beta^{II}] = 0 \]  

Note that \( \mathcal{E} \mathcal{E} \) operators do not mix negative and positive energy solutions of the neither 1\textsuperscript{st} and 2\textsuperscript{nd} particle whereas \( \mathcal{O} \mathcal{O} \) mix both and \( \mathcal{O} \mathcal{E}(\mathcal{E} \mathcal{O}) \) mix only the negative and positive energy solutions of the 1\textsuperscript{st}(2\textsuperscript{nd}) particles.

The idea behind the Foldy-Wouthuysen transformation is to make a unitary transformation,

\[ \Psi' = e^{iS} \Psi \]  

so that in the transformed Hamiltonian,

\[ \frac{\partial}{\partial t} \Psi' = \frac{\partial}{\partial t}(e^{iS} \Psi) = e^{iS} \frac{\partial}{\partial t} \Psi = e^{iS} H e^{-iS} e^{iS} \Psi = H' \Psi' \]

\[ H' = e^{iS} H e^{-iS} \]

the operators that result in mixing only contributes to the in the order \( 1/m^4 \). Determination of the operator \( S \) in the case of one particle is very easy: First one expresses the transformed Hamiltonian as series expansion

\[ H' = H + i [S, H] - \frac{1}{2!} [S, [S, H]] + \ldots \]  

then requires the transformed Hamiltonian not to include the operators that mix negative and positive energy solutions at the first order. Therefore for a general case of Hamiltonian for one particle,

\[ H = \mathcal{E} + \mathcal{O} + \beta m \]  

one chooses \( S = -i\beta \mathcal{O}/m \) so that the transformed Hamiltonian includes the odd operator only at second order \( (1/m^2) \). For the case of two particles

\[ H = \mathcal{E} \mathcal{E} + \mathcal{O} \mathcal{E} + \mathcal{E} \mathcal{O} + \mathcal{O} \mathcal{O} + \beta^I m_I + \beta^{II} m_{II} \]  

the transformation is given as\[11]\,,
for particles with different mass, \( m_I \neq m_{II} \). But for the case of equal masses obtaining \( S \) is a formidable task and the resulting tedious formula can be found at [11]. At first sight one might think that the formula given above can not be used for our case where the Hamiltonian is given by,

\[
H_B = H_I + H_{II} + U_B(r)
\]

(A.17)

where, in CM coordinates,

\[
H_I = \alpha^I \cdot p^I + \beta^I m_q = \alpha^I \cdot p + \beta^I m_q
\]

(A.18)

\[
H_{II} = \alpha^{II} \cdot p^{II} + \beta^{II} m_q = -\alpha^{II} \cdot p + \beta^{II} m_q
\]

(A.19)

\[
U_B(r) = -\left(\frac{4 \alpha_s}{3 r}\right) \frac{1}{r} \left[ 1 - \frac{\alpha^I \cdot \alpha^{II}}{2} + \frac{(\alpha^I \cdot r_{12})(\alpha^{II} \cdot r_{12})}{2r^3} \right]
\]

(A.20)

But a clever observation by [1] makes the above formula usable. The reasoning follows as, since we are interested in separating negative and positive energy solutions, we might as well do the separation in the beginning using the projection operators

\[
\Lambda^I_\pm = \frac{E_I \pm H_I}{2E_I} \quad \Lambda^I_\pm = \frac{E_{II} \pm H_{II}}{2E_{II}}
\]

(A.21)

where

\[
E_I = \sqrt{m_I^2 + p^2} \quad E_{II} = \sqrt{m_{II}^2 + p^2}
\]

(A.22)

In [11] this observation is made rigorous by considering, instead of our starting Hamiltonian, the Hermitian part of the three-dimensional Bethe-Salpeter equation written in coordinate space given as,

\[
H \Psi(r) = \left( H_I + H_{II} + \frac{1}{2} \left[ \left( \Lambda^I_+ \Lambda^{II}_+ - \Lambda^I_- \Lambda^{II}_- \right), H_B(r) \right] \right) \Psi(r) = E \Psi(r)
\]

(A.23)

We now evaluate the anti-commutator of \( U_B(r) \) with the projection operators. Noting that

\[
\Lambda^I_+ \Lambda^{II}_+ - \Lambda^I_- \Lambda^{II}_- = \frac{(E_I + H_I)(E_{II} + H_{II})}{E_I E_{II}} - \frac{(E_I - H_I)(E_{II} - H_{II})}{E_I E_{II}}
\]

(A.24)

\[
= \frac{E_{II} H_I}{E_I E_{II}} + \frac{E_I H_{II}}{E_I E_{II}}
\]

(A.25)

\[
= \frac{H_I}{E_I} + \frac{H_{II}}{E_{II}}
\]

(A.26)
therefore,
\[
\frac{1}{2} \left[ \left\{ \Lambda_I^{\mu} \Lambda_{II}^{\mu} - \Lambda_I^{\mu} \Lambda_{II}^{\mu} \right\}, H_B(r) \right]_+ = \frac{1}{2} \left[ \frac{H_I}{E_I} + \frac{H_{II}}{E_{II}}, H_I \right]_+ + \frac{1}{2} \left[ \frac{H_I}{E_I} + \frac{H_{II}}{E_{II}}, H_I \right]_+ + \frac{1}{2} \left[ \frac{H_I}{E_I} + \frac{H_{II}}{E_{II}}, U_B \right]_+ \tag{A.27}
\]
\[
\frac{1}{2} \left[ \left\{ \Lambda_I^{\mu} \Lambda_{II}^{\mu} - \Lambda_I^{\mu} \Lambda_{II}^{\mu} \right\}, H_B(r) \right]_+ = \frac{1}{2} \left[ \frac{H_I}{E_I} + \frac{H_{II}}{E_{II}}, H_I \right]_+ + \frac{1}{2} \left[ \frac{H_I}{E_I} + \frac{H_{II}}{E_{II}}, H_I \right]_+ + \frac{1}{2} \left[ \frac{H_I}{E_I} + \frac{H_{II}}{E_{II}}, U_B \right]_+ \tag{A.28}
\]
\[
\frac{1}{2} \left[ \left\{ \Lambda_I^{\mu} \Lambda_{II}^{\mu} - \Lambda_I^{\mu} \Lambda_{II}^{\mu} \right\}, H_B(r) \right]_+ = \frac{1}{2} \left[ \frac{H_I}{E_I} + \frac{H_{II}}{E_{II}}, H_I \right]_+ + \frac{1}{2} \left[ \frac{H_I}{E_I} + \frac{H_{II}}{E_{II}}, H_I \right]_+ + \frac{1}{2} \left[ \frac{H_I}{E_I} + \frac{H_{II}}{E_{II}}, U_B \right]_+ \tag{A.29}
\]

Now observe that, for example,
\[
\left[ H_I^{1}, H_I^{(r)} \right]_+ = \frac{H_I}{m^2} + \frac{1}{m^2} \left[ \frac{H_I}{m} - \frac{1}{m^2} \frac{p}{m} + \ldots, H_I^{(r)} \right]_+ \tag{A.30}
\]
\[
\text{where we have expanded in the powers of } \frac{p}{m} \text{. But we are only interested in the terms up to order } \frac{1}{m^2}, \text{ therefore discarding the higher order we arrive at.}
\]
\[
\left[ H_I^{1}, H_I^{(r)} \right]_+ = \frac{1}{m^2} \left[ H_I p, H_I^{(r)} \right]_+ \tag{A.31}
\]
\[
\text{Carrying out a similar analysis in all terms, we compute the commutation of } H_B \text{ and positive and negative energy projectors, up to order } \frac{1}{m^2}, \text{ which is given as,}
\]
\[
H_I + H_{II} + \frac{1}{2} \left[ \left\{ \Lambda_I^{\mu} \Lambda_{II}^{\mu} - \Lambda_I^{\mu} \Lambda_{II}^{\mu} \right\}, H_B(r) \right]_+ = EE + OE + OO \tag{A.32}
\]
\[
\text{where,}
\]
\[
EE = \frac{e}{2r} \left( \beta_I^{\mu} + \beta_{II}^{\mu} \right) - \frac{e}{8m^2} \left( \beta_I^{\mu} + \beta_{II}^{\mu} \right) \left[ p^2, \frac{1}{r} \right]_+ \tag{A.33}
\]
\[
OE = \alpha_I^{\mu} \cdot p + \frac{3e}{8m} \left[ \alpha_I^{\mu} \cdot p, \frac{1}{r} \right]_+ + \frac{i e}{8m} \sigma^{II} \cdot \left[ \sigma^{II}, \frac{1}{r} \right]_+ \tag{A.34}
\]
\[
OE = \alpha_I^{\mu} \cdot p + \frac{3e}{8m} \left[ \alpha_I^{\mu} \cdot p, \frac{1}{r} \right]_+ + \frac{i e}{8m} \sigma^{II} \cdot \left[ \sigma^{II}, \frac{1}{r} \right]_+ \tag{A.35}
\]
\[
EO = -\alpha_{II}^{\mu} \cdot p - \frac{3e}{8m} \left[ \alpha_{II}^{\mu} \cdot p, \frac{1}{r} \right]_+ - \frac{i e}{8m} \sigma^{II} \cdot \left[ \sigma^{II}, \frac{1}{r} \right]_+ \tag{A.36}
\]
\[
EO = -\alpha_{II}^{\mu} \cdot p - \frac{3e}{8m} \left[ \alpha_{II}^{\mu} \cdot p, \frac{1}{r} \right]_+ - \frac{i e}{8m} \sigma^{II} \cdot \left[ \sigma^{II}, \frac{1}{r} \right]_+ \tag{A.37}
\]
\[
EO = -\alpha_{II}^{\mu} \cdot p - \frac{3e}{8m} \left[ \alpha_{II}^{\mu} \cdot p, \frac{1}{r} \right]_+ - \frac{i e}{8m} \sigma^{II} \cdot \left[ \sigma^{II}, \frac{1}{r} \right]_+ \tag{A.38}
\]
Now Substituting above terms in Eqn[A.16] gives the desired Breit-Fermi interaction terms.

\[
H_{BF} = -\frac{4}{3} \frac{\alpha_s}{r} \left( \frac{p^2}{m} - \frac{p^4}{4m^3} \right) - 2m + \frac{p^2}{m} \cdot \frac{p^4}{4m^3} - \frac{2}{3} \frac{\alpha_s}{m_q} \left( \frac{p^2}{r} + \frac{r(r \cdot p) \cdot p}{r^3} \right) + \frac{4}{3} \frac{\alpha_s}{m_q} \delta(r) \left( 1 + \frac{8\pi}{3} S_1 \cdot S_2 \right) + 2 \frac{\alpha_s}{m_q} \left( (S_1 + S_2) \cdot L \right) + \frac{4}{3} \frac{\alpha_s}{m_q^2 r^3} \left( \frac{3(S_1 \cdot r)(S_2 \cdot r)}{r^2} - S_1 \cdot S_2 \right)
\]
APPENDIX B

TENSOR INTERACTION COEFFICIENTS

In this part given the tensor interaction

\[ V_{\text{Tensor}} = \frac{4}{3} \frac{\alpha_s}{m^2 r^3} \left( 3 \frac{(S_1 \cdot r)(S_2 \cdot r)}{r^2} - S_1 \cdot S_2 \right) \]  

we are interested in evaluating matrix elements of the tensor interaction coefficients,

\[ \langle 3 \frac{(S_1 \cdot r)(S_2 \cdot r)}{r^2} - S_1 \cdot S_2 \rangle = \langle T_{12} \rangle \]  

Noting that,

\[ (S \cdot r)^2 = (S_1 \cdot r)^2 + (S_2 \cdot r)^2 + 2(S_2 \cdot r)(S_1 \cdot r) \]  

\[ = \frac{1}{4} (\sigma_1 \cdot r)^2 + \frac{1}{4} (\sigma_2 \cdot r)^2 + 2(S_2 \cdot r)(S_1 \cdot r) \]  

\[ = \frac{1}{2} r^2 + 2(S_2 \cdot r)(S_1 \cdot r) \]

and

\[ S_1 \cdot S_2 = \frac{1}{2} (S^2 - S_1^2 - S_2^2) \]  

\[ = \frac{1}{2} (S^2 - \frac{3}{2}) \]

We obtain the coefficient in terms of the total spin operator.

\[ \frac{1}{2} \left( 3 \frac{(S \cdot r)^2}{r^2} - S^2 \right) \]  

In spherical coordinates the total spin matrix is given as,

\[ S = S_x \hat{x} + S_y \hat{y} + S_z \hat{z} \quad \mathbf{r} = r(\sin \theta \cos \phi \hat{x} + \sin \theta \sin \phi \hat{y} + \cos \theta \hat{z}) \]
Therefore the scalar product is,

\[
\frac{(S \cdot r)^2}{r^2} = S_x^2 \sin^2 \theta \cos^2 \phi + S_y^2 \sin^2 \theta \sin^2 \phi + S_z^2 \cos^2 \theta \\
+ (S_x S_y + S_y S_x) \sin^2 \theta \cos \phi \sin \phi \\
+ (S_x S_z + S_z S_x) \sin \theta \cos \phi \\
+ (S_y S_z + S_z S_y) \sin \theta \cos \sin \phi
\]  
(B.10)  
(B.11)  
(B.12)  
(B.13)

We are interested in finding the matrix elements in the \( \langle j', l', s', m'_s | j, l, s, m_j \rangle \) basis, which can be expressed as,

\[
\Sigma \langle j, l, s, m_j | l', m'_l, s', m'_s \rangle \{ \langle l', m'_l, s', m'_s | T_{12} | l'', m''_l, s'', m''_s \rangle \} \langle l'', m''_l, s'', m''_s | j, l, s, m_j \rangle \]
(B.14)

where the summation is over primed and double primed states. Evaluating the matrix elements in the curly brackets and expressing the various combinations of sine and cosine terms in terms of spherical harmonics, we find,

\[
\langle l', m'_l, s', m'_s | T_{12} | l'', m''_l, s'', m''_s \rangle =
\]  
(B.15)

\[
c_{++} \left( \frac{2\pi}{3} \right) \langle l', m'_l, s', m'_s | Y_1^{-1} | l'', m''_l, s'', m''_s + 2 \rangle \\
+ c_{--} \left( \frac{2\pi}{3} \right) \langle l', m'_l, s', m'_s | Y_1^1 | l'', m''_l, s'', m''_s - 2 \rangle \\
+ \left( \frac{2\pi}{3} \right) \langle l', m'_l, s', m'_s | Y_1^{-1} \sin Y_1^0 + 2m''_s(Y_1^0)^2 | l'', m''_l, s'', m''_s \rangle \\
+ c_+ \left( \frac{2\sqrt{2}\pi}{3} \right) (2m''_s + 1) \langle l', m'_l, s', m'_s | Y_1^{-1} Y_1^0 | l'', m''_l, s'', m''_s + 1 \rangle \\
+ c_- \left( \frac{2\sqrt{2}\pi}{3} \right) (2m''_s - 1) \langle l', m'_l, s', m'_s | Y_1^1 Y_1^0 | l'', m''_l, s'', m''_s - 1 \rangle
\]  
(B.16)  
(B.17)  
(B.18)  
(B.19)  
(B.20)

where coefficients arising from the action of raising and lowering operators are,

\[
c_{++} = \sqrt{(j'' - m'')(j'' + m'' + 1)} \sqrt{(j'' - m'' - 1)(j'' + m'' + 2)} \\
+c_{--} = \sqrt{(j'' + m'' - 1)(j'' - m'' + 2)} \sqrt{(j'' + m'')(j'' - m'' + 1)} \\
c_+ = \sqrt{(j'' - m'')(j'' - m'' + 1)} \\
c_- = \sqrt{(j'' + m'')(j'' - m'' + 1)} \\
c_0 = 2(j''(j'' + 1) - m'')
\]  
(B.21)  
(B.22)  
(B.23)  
(B.24)
To evaluate the spherical harmonics together with the inner product of $|lm_l⟩$ states we use the $3jm$ symbols to evaluate the integral between the products of three spherical harmonics

$$\int Y_{l_1}^{m_1} Y_{l_2}^{m_2} Y_{l_3}^{m_3} \sin \theta d\theta d\phi = N_2(l_1, l_2, l_3) \begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix}$$

(B.25)

where,

$$\begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix} = \left( \frac{(-1)^{j_1-j_2-m_3}}{\sqrt{2j_3+1}} \right) \langle j_1 m_1 j_2 m_2 | j_3 - m_3 \rangle$$

(B.26)

and

$$N_3(l_1, l_2, l_3) = \sqrt{(2l_1+1)(2l_2+1)(2l_3+1)} / 4\pi$$

(B.27)

Therefore for example the first term gives

$$c_+ \left( \frac{2\pi}{3} \right) \langle l', m'_l, s', m'_s | Y_1^{-1} | l'', m''_l, s'', m''_s + 2 \rangle$$

(B.28)

$$= c_+ \left( \frac{2\pi}{3} \right) \langle l', m'_l | Y_1^{-1} | l'', m''_l \rangle \delta_{s',s''} \delta_{m'_i,m''_i} + 2$$

(B.29)

$$= c_+ \left( \frac{2\pi}{3} \right) \left\{ \int Y_{l'}^{m'_l} Y_1^{-1} Y_{l''}^{m''_l} \sin \theta d\theta d\phi \right\} \delta_{s',s''} \delta_{m'_i,m''_i} + 2$$

(B.30)

$$= c_+ \left( \frac{2\pi}{3} \right) N_2(l_1, l_2, l_3) \begin{pmatrix} l' & 1 & l'' \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l' & 1 & l'' \\ -m'_l & -1 & m''_l \end{pmatrix} \delta_{s',s''} \delta_{m'_i,m''_i} + 2$$

(B.31)

Next the remaining Clebsch Gordon coefficients are expressed in terms of $3jm$ symbols, using Eqn[B.26], which we will show only for the first term,

$$= \sum_{s',m''_i} \begin{pmatrix} l' & 1 & j \end{pmatrix} \begin{pmatrix} l' & 1 & l'' \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l' & 1 & l'' \\ -m'_l & -1 & m''_l \end{pmatrix} \begin{pmatrix} l' & 1 & j \end{pmatrix}$$

(B.32)

Where we have used the orthogonality relation to deduce, $m''_i = -m'_i = -1$. Using the selection rules we obtain $m_j = 1 - m_j$, and using the orthogonality relations by carrying out the summations, and carrying out a similar analysis in all terms one finds that the tensor operator has non-vanishing diagonal matrix elements only between $L > 0$ spin-triplet states.
and its value is given by

\[
T_{Tensor} = 3 \frac{(\vec{S}_i \cdot r)(\vec{S}_j \cdot r)}{r^2} - \vec{S}_i \cdot \vec{S}_j = \begin{cases} 
-\frac{l}{2(2l+3)} & J = L + 1 \\
1/2 & J = L \\
-\frac{(l+1)}{3(2l-1)} & J = L - 1 \\
0 & L = 0 \text{ or } S = 0
\end{cases}
\] (B.33)
