September 2015, 90 pages

Osteomyelitis is a difficult to treat bone infection. In clinic, osteomyelitis is treated with surgical debridement followed by the antibiotic therapy. But, due to the low blood circulation in the infection area and the production of an exopolysaccharide, biofilm, by the pathogen violence the treatment. Therefore local drug delivery systems are generated. These systems transmit the effective dose to the infection area without any toxic effects.

In this study, vancomycin containing PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites were developed and characterized. Vancomycin containing PDLLA/ $\beta$ -TCP and vancomycin containing PLGA/ $\beta$ -TCP composites released  $3.1 \pm 0.2$  mg and  $3.4 \pm 0.4$  mg vancomycin for six weeks, respectively and the released vancomycin was sufficient for MRSA susceptibility. Also, the released vancomycin inhibited the biofilm formation of Methicillin Resistant *S. aureus*. Vancomycin containing PDLLA/ $\beta$ -TCP and vancomycin containing PLGA/ $\beta$ -TCP composites were biocompatible with Mesenchymal Stem Cells and SaOS-2 osteosarcoma cells.

The composites showed alkaline phosphatase activity at day 21. But for the RT-PCR studies conducted with the extraction medium of the composites, the vancomycin

containing PDLLA/ $\beta$ -TCP and vancomycin containing PLGA/ $\beta$ -TCP composites were not induced the differentiation of mesenchymal stem cells by not expressing some of the osteogenesis related signalling molecules.

**Keywords:** Antibiotic, osteomyelitis, PDLLA, PLGA, vancomycin, bone, polymer, MRSA, drug delivery systems, controlled release, biodegradable polymer, biofilm

## ÖZ

# VANKOMİSİN İÇEREN BİYOSERAMİK/POLİMER KOMPOZİTLERİN BİYOFİLİM ENGELLEMESİ, BİYUYUMLULUĞU VE MEZENKİMAL KÖK HÜCRELERİN OSTEOJENİK DEĞİŞİMLERİ ÜZERİNE ETKİLERİNİN ANALİZİ

Osteomyelit tedavisi oldukça zor bir kemik enfeksiyonudur. Klinikte osteomyelit tedavisi cerrahi debridman sonrası sistemik olarak verilen antibiyotikler ile sağlanmaktadır. Ancak enfeksiyon bölgesinde yeterli kan akışının olmaması ve enfeksiyon yaratan patojenin biyofilim adı verilen ekzopolisakkarit yapının içinde antibiyotiklere karşı dirençli olması nedeniyle enfeksiyon tam anlamıyla yok edilememektedir. Bu nedenle enfeksiyon bölgesine ilaç taşıyıcı sistem yerleştirme fikri doğmuştur. Bu sistemler vücutta herhangi bir toksik etki yaratmadan direkt olarak enfeksiyon bölgesine etkin dozu ulaştırmaktadır.

Gerçekleştirilen çalışmada vankomisin içeren PDLLA/ $\beta$ -TCP ve PLGA/ $\beta$ -TCP kompozitler geliştirilmiş ve karakterize edilmiştir. Vankomisin içeren PDLLA/ $\beta$ -TCP ve PLGA/ $\beta$ -TCP kompozitler altı hafta boyunca  $3.1 \pm 0.2$  mg ve  $3.4 \pm 0.4$  mg vankomisin salmıştır ve salınan miktar MRSA duyarlılığı için yeterlidir. Ayrıca salım ortamlarından alınan örneklerle gerçekleştirilen biyofilm oluşumu engelleme çalışmasında, geliştirilen kompozitlerin MRSA biyofilm oluşumunu engellediği gösterilmiştir. Geliştirilen kompozitler mezenkimal kök hücreler ve SaOS-2

osteosarkoma hücreleri ile biyouyumludur. Ayrıca, kompozitlerin hücrelerle 21 günlük kültürü sonunda hücreler alkalın fosfataz aktivitesi göstermiştir. Ancak, kompozitlerden salınan maddelerin bulunduđu besiyerlerinin kullanıldığı RT-PCR çalışmasında kompozit grupları bazı osteogenez ilintili sinyal moleküllerini ifade etmeyerek mezenkimal kök hücrelerin farklanmasını tetiklememiştir.

**Anahtar Kelimeler:** Antibiyotik, osteomyelit, PDLLA, PLGA, vankomisin, kemik, polimer, MRSA, biyouyumluluk, ilaç taşıyıcı sistemler, kontrollü salım, biyobozunur polimer, biyofilim

## ACKNOWLEDGEMENTS

First of all, I would like to express my gratitudes to my supervisor Prof. Dr. Erdal Bayramlı for his support and help. I would like to thank my co supervisor Prof. Dr. Feza Korkusuz for his support and guidance through the study.

I would like to thank Prof. Dr Duygu Uçkan Çetinkaya, Assoc. Prof. Dr. Ayşen Günel Özcan, Assist. Prof Dr. Fatima Aerts Kaya, Dr. Betül Çelebi Saltık and all the members of Hacettepe University Stem Cell Research and Application Center for their helps during my study.

I want to express my thanks to Prof Dr Petek Korkusuz for her support. I also would like to thank Prof Dr. Burçin Şener for her guidance during the microbiological studies and for providing the bacterial strains. I would like to thank Dr Pelin Mutlu for PCR studies.

I would like to express my gratitudes to my dear friend Sevil Köse for her support.

At the end, I would like to thank my beloved friends Ilgın Çağnan and Dr. Çağla Köprü for their helps and supports through the study.

Lastly, I would like to thank my dear husband Coşkun Serhat Kankılıç and my family for their helps and supports during this long way.

## CHAPTER 1

### INTRODUCTION

Osteomyelitis is a difficult to treat orthopedic infection, which arose as a result of the colonization of pathogens, especially the most causative organism methicillin resistant *Staphylococcus aureus* (MRSA) (1). The treatment of osteomyelitis is generally done with surgical debridement and parenteral antibiotic administration up to six weeks (2).

In parenteral antibiotic administration, the antibiotic reached to the infection area cannot eradicate the pathogen, since only lower amounts of antibiotic can reach to infection area due to low blood circulation and the circulated amount is lower than the minimum inhibitory concentration. Also, the pathogen can capable of forming a biofilm in the infection area. Biofilms protect the pathogen from immune defenses and they are resistant to antibiotics, so the parenteral antibiotic cannot eradicate the pathogen (3).

Drug delivery systems are developed in order to control and treat bone infections. In drug release systems, biodegradable and biocompatible polymers or bioceramics carries drugs. In some cases, both kinds of materials are used to minimize each material's disadvantages and composites are developed. These drug delivery systems should be active against the pathogen involved in the infection, release antibiotic at least ten times higher than the minimum inhibitory concentration of the pathogen, not evoke any immune response (4).

Poly (D, L-lactide) (PDLLA) and poly (D, L-lactide-co-glycolide) (PLGA) are biodegradable and biocompatible polymers generally used as carrier in drug delivery systems (5). The disadvantages of these polymers are their acidic products after the biodegradation. The acidic products decrease the pH of the environment and fasten the further degradation. Also, these polymers have low cell adhesion potential (6).

Beta-tricalcium phosphate ( $\beta$ -TCP) is a biodegradable bioceramic used in local drug delivery systems. The bioceramic has high solubility rate, and degrades faster (2), (7). It also shows osteointegration and osteoconduction properties (8).

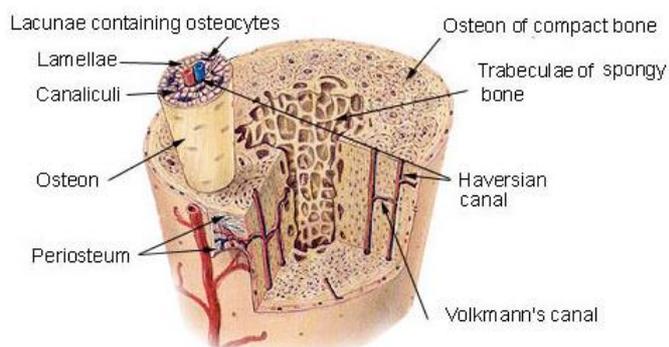

From this point of view, we developed two different drug release systems; vancomycin containing PDLLA/ $\beta$ -TCP composites and vancomycin containing PLGA/ $\beta$ -TCP composites and searched for their biofilm inhibition potential and biocompatibility with mesenchymal stem cells.

## CHAPTER 2

### BACKGROUND INFORMATION

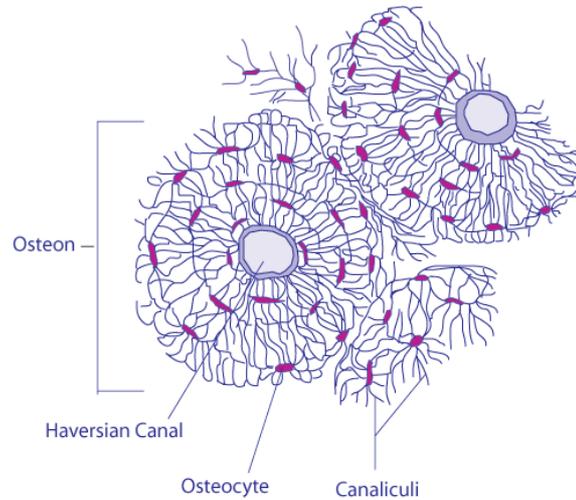

#### 2.1 Bone

Bone is a tissue that supports and protects the organs, provides motility, stores minerals and produces red and white blood cells. Bone is made up of organic compartment type 1 collagen, inorganic compartment carbonate hydroxyapatite ( $\text{Ca, Mg, Na}_{10}(\text{PO}_4, \text{CO}_3)_6(\text{OH})_2$ ) and water (9). The organic compartment, type I collagen, gives rigidity while inorganic compartment, hydroxyapatite, gives the elasticity to the tissue.

**Figure 1.** The structure of bone (10).

The outer layer of the bone is called cortical or compact bone. The primary functional unit of cortical bone is called osteon. Osteons are connected to each other and the periosteum, the membrane covering the bone, by Volkmann's canals. Volkmann's canal provides energy and nourishing elements for osteon (Figure 1). Each osteon also surrounds Haversian canal, which protects blood vessels and nerve cells of the bone and enables the communication between osteocytes by canaliculi (Figure 2) (11).

**Figure 2.** The structure of an osteon (12).

Osteocyte is a star shaped bone cell derived from osteoprogenitor cells and embedded in bone matrix. They can differentiate into osteoblasts and osteoids. Osteocytes regulate mineral homeostasis by resorbing the bone with their osteocytic osteolysis function and have mechanosensory mechanisms (13). Osteoblast is another type of bone cell responsible from bone formation. Mesenchymal stem cells (MSC) or osteoprogenitor cells differentiate into preosteoblasts and then to mature osteoblasts. The unmineralized organic portion of bone matrix forms prior to bone tissue formation is known as osteoid or bone extracellular matrix (ECM) is secreted by these osteoblasts and as the osteoid becomes mineralized, osteoblasts are trapped in lacunae and osteocyte become bone lining cells (14). Osteoclasts are another bone cell type that degrade the mineralized bone and bone ECM by secreting proteolytic enzymes and acids and derived from hematopoietic cells (11, 15). The ECM of bone consists of collagens, proteoglycans, glycosaminoglycans and glycoproteins like alkaline phosphatase osteonectin, osteocalcin, bone sialoprotein and osteopontin. Bone ECM upregulates or downregulates the signaling pathways and regulates bone cells while providing the mechanical property of bone (14).

Spongy bone, also known as trabecular or cancellous bone, is another type of osseous tissue found at the ends of long bones. This tissue has higher vascularity and responsible from production of blood cells (11).

### **2.1.1 Bone Formation**

The bone is formed by two mechanisms: intramembranous ossification and endochondral ossification. In intramembranous ossification, MSC differentiate into osteoblasts and form an ossification center. Osteoblasts secrete osteoid and it begins to calcify. The osteoblasts trapped in calcified osteoid become osteocytes and by the entrapment of osteocytes on mesenchymal surface, periosteum forms. Later, the mineral deposition continues leads to creation of trabeculae and forms the spongy bone. Finally, the trabeculae under the periosteum thicken and replaced with lamellar bone and form compact bone plates. Spongy bone stays internally and its vascular tissue becomes red marrow. Flat bones of skull, mandible and maxilla are formed by intramembranous ossification (16). In endochondral ossification, a hyaline cartilage model grows by cell division of chondrocytes. As the chondrocytes become mature, hyaline cartilage model begins to calcify. The perichondrium around the hyaline cartilage vascularizes and becomes periosteum. The osteoprogenitor cells in the periosteum use calcified matrix and becomes osteoblasts. The osteoblasts secrete osteoid and form trabeculae. The ossification of long bones and bone fracture healing is followed by endochondral ossification (17).

In bone formation and regeneration, many signaling molecules are essential. Some of these signaling molecules like transforming growth factor beta (TGF- $\beta$ ), bone morphogenetic proteins (BMPs), and growth differentiation factors (GDFs) belong to TGF- $\beta$  superfamily. TGF- $\beta$  induces MSC, chondrocyte, preosteoblast and osteoblast proliferation and collagen, proteoglycan, osteopontin, osteonectin and alkaline phosphatase production (8). It triggers the BMP synthesis and induces the inhibition of osteoclast activity (13). BMPs are responsible from osteogenesis, mesenchymal and osteoprogenitor cell proliferation, differentiation and bone extracellular matrix synthesis. BMPs are divided into four groups: BMP-2 and BMP-4 form group 1, BMP-5, BMP-6 and BMP-7 form group 2, BMP-12, BMP-13 and BMP-14 form group 3 and BMP-3 and BMP-3b form group 4. BMP-3 is an antagonist to other BMPs and it down regulates the bone density. Unlike the other BMPs, BMP-1 induces the development of bone and cartilage but it does not belong to TGF- $\beta$

superfamily (18). BMPs bind to serine/threonine kinase receptors and initiate Smad signaling. Smad family has eight members and divided into three groups. The receptor regulated Smads (SMAD 1, 2, 3, 5 and 8), common mediator Smad (SMAD 4) and the inhibitory Smads (SMAD 6 and 7). Once the Smads are activated, they regulate the transcription of target genes (19). BMPs also induce the secretion of other growth factors like insulin like growth factors (IGFs) and vascular endothelial growth factors (VEGFs) (20). IGFs are secreted from osteoblasts, chondrocytes, bone matrix and endothelial cells. IGF-1 induces the formation of bone matrix while IGF-2 stimulates cellular proliferation and type 1 collagen production (21). Nearly at the end of endochondral ossification, cartilage and bone are degraded to induce the angiogenesis by VEGF dependent pathway. VEGF expressed by osteoblasts and osteoblast like cells is stimulated by BMPs (22). Platelet derived growth factor (PDGF) is another growth factor expressed by macrophages, osteoblasts and platelets for the proliferation of MSCs and osteoblasts (19). Fibroblast growth factor (FGF) is also expressed by macrophages, osteoblasts and MSCs and it triggers the cell division of MSCs and osteoblasts (23).

Besides the growth factors, matrix metalloproteinases secreted by macrophages degrade the bone ECM and they are essential for bone formation (23, 24). There are also many transcription factors that regulate bone formation according to osteoblast differentiation and they control the expression of many ECM protein genes or osteogenic genes during the differentiation. Runt related transcription factor (RUNX2) is a transcription factor responsible from the differentiation of osteoblasts. It also regulates the expression of alpha-1 type I collagen (COL1A1), alpha-2 type I collagen (COL1A2) and bone gamma carboxyglutamate (gla) protein (BGLAP). During the differentiation of mature osteoblasts into osteocytes, mature osteoblasts express BGLAP while osteocytes express dentin matrix protein 1. Runx2 is a leading gene expressed during bone formation; since this gene is expressed by osteoblasts and without osteoblasts there will not be any bone formation (25).

### **2.1.2 Mesenchymal Stem Cells (MSCs)**

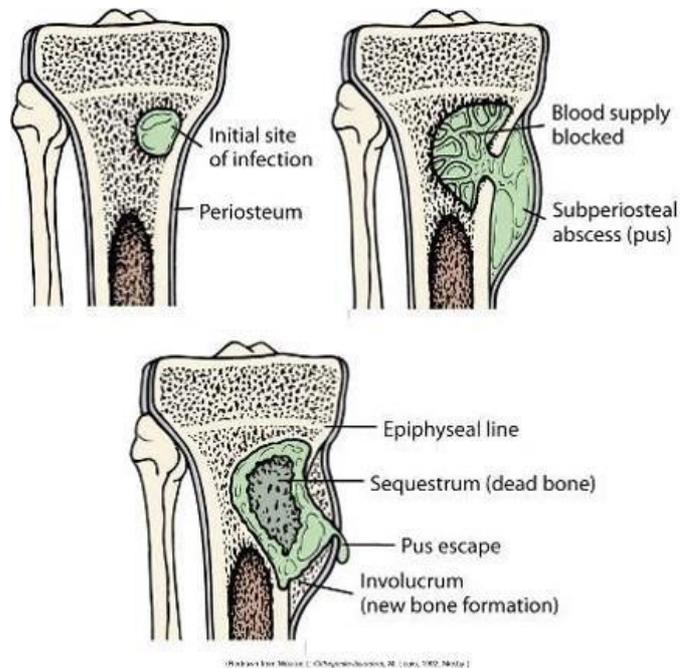

Mesenchymal stem cells found in bone marrow have self-renewal ability and they

can differentiate into many cell types like bone, fat, cartilage, muscle (26, 27). They can be easily isolated and expanded *in vitro*, therefore they are frequently used in regenerative medicine and tissue engineering (28). After the signaling of major molecules interleukin 1 and 6 (IL-1 and IL-6) in the inflammation of bone, fracture repairment is followed by the signaling of TGF- $\beta$ , IGF, FGF, PDGF, BMPs and VEGF. All these signaling molecules induced the proliferation and differentiation of MSCs (17, 22, 29, 30). In the regeneration or formation of the bone, mesenchymal stem cells are activated and they can differentiate into osteoblasts and chondrocytes. Once MSCs differentiate into chondrocytes, they can form the bone by endochondral ossification. MSCs can be isolated from various sources in the body like, bone marrow, mineralized bone and adipose tissue. BMP and FGF signaling pathways influence the differentiation of MSCs (31). MSCs can be induced to differentiate into osteoblasts *in vitro* by using dexamethasone, L-ascorbic acid and beta glycerophosphate during cell culturing (23, 32).

## **2.2 Osteomyelitis**

Osteomyelitis is an inflammatory difficult to treat bone infection caused by pyogenic bacteria which are capable to form pus (33). The infection is generally arisen secondary from a contiguous focus of infection such as trauma, surgery or vascular insufficiency and hematogenous spread (34). Osteomyelitis can be classified as acute or chronic osteomyelitis; acute osteomyelitis lasts for days and weeks while chronic osteomyelitis lasts for months or years (35).

In the mechanism of infection, microorganisms adhere to host bone tissue with their adhesins specific for host proteins like collagen, fibronectin and bone sialoprotein (36). Macrophages attack to the pathogen, release proteolytic enzymes and leads to tissue lysate. In the manner of adaptive immunity, pus spreads to vascular channels in the bone and deteriorate blood flow (37). As the infection progresses to chronic state, necrotic bone is fragmented and sequestrum is formed (Figure 3) (34). Chronic osteomyelitis is generally treated with surgical debridement and four to six week lasting parenteral antibiotic therapy (38).

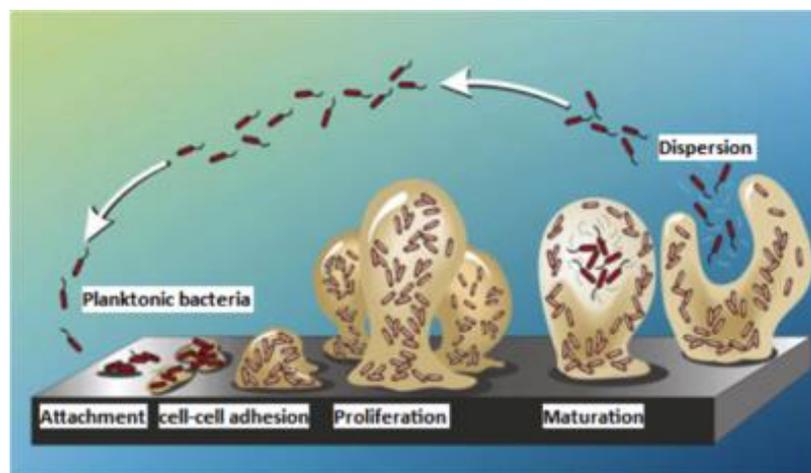

**Figure 3.** Illustration of osteomyelitis (39)

Methicillin resistant *Staphylococcus aureus* (MRSA) is the most common pathogen isolated from the infection site but other pathogens like *Staphylococcus epidermidis*, coagulase-negative staphylococci, *Enterobacter* species, *Pseudomonas aeruginosa* and *Mycobacterium* species are also responsible for osteomyelitis. *Staphylococcus aureus* is a gram positive, facultative anaerobe. It has a spherical shape with 0.5 to 1.5  $\mu\text{m}$  diameter and forms bead like clusters when colonized. *Staphylococcus aureus* is naturally found in human skin and nostrils. It attaches to the surface with its adhesins and exotoxins and many of its strains are capable of forming biofilm. Biofilm protects the pathogen from environmental conditions like antibiotics and phagocytosis (40).

### 2.2.1 Biofilm

Biofilm is a three dimensional extracellular polymeric matrix formed by the irreversible attachment of the *Staphylococcus aureus* to a surface (41). Once *Staphylococcus aureus* attach to a surface, it begins to produce multi-layered

biofilms under glycocalyx, or slime layer (35). Gross et al. found that teichoic acids found in the pathogen are the leading cause for biofilm formation (42). Besides, polysaccharide intercellular adhesin (PIA) is also responsible for biofilm formation (43). In a biofilm environment, bacteria can communicate with chemotaxis, known as quorum sensing when they reach to a threshold cell density (44). Biofilm protects the bacteria from outer environmental conditions like antibiotic agents, phagocytosis, oxygen radical and protease defenses. As biofilm decreases the permeability of antimicrobial agents by acting as a diffusion barrier, in order to eradicate the bacteria within the biofilm, higher concentrations of antimicrobial agents are needed (45). Also under the protection of a biofilm, mature bacteria colonies can detach from the biofilm and they can migrate and form new biofilms in uninfected areas (46) (Figure 4).

**Figure 4.** The stages of biofilm formation (47).

Biofilms can be detected by various techniques like tissue culture plate, tube method, Congo Red Agar method, bioluminescent assay, and fluorescent microscopy. In tissue culture plate method, which is the major biofilm detection technique, biofilm forming bacteria are inoculated into 1% glucose containing trypticase soy broth. Bacteria culture is placed in 96 well tissue culture plate as 200  $\mu$ l per well. The plate is incubated at 37°C for 24-48 hours. After, planktonic bacteria are poured out and wells are washed. The wells are filled with 0.1% crystal violet stain and then washed with water to get rid of the excess stain. Remaining crystal violet stain is solubilized

with 95% ethanol and optical density (OD) is measured in ELISA reader at 620 nm (48). In another technique; tube method, bacteria are again inoculated in 1% glucose containing trypticase soy broth but this time test tubes are used instead of a tissue culture plate. Same procedures are carried out like in tissue culture method but at the end this time biofilm formation is detected qualitatively according to control strains. Biofilm formation is scored as weak/none, moderate or strong. In Congo Red Agar method, Congo Red indicator is added to sucrose containing brain heart infusion agar. Microorganisms are inoculated into Congo Red Agar plates and incubated at 37° for 24 hours. Dry crystals containing black colonies give qualitative biofilm formation (45). Xiong et al. monitored the biofilm formation in a mouse infection model with bioluminescent bacteria (49). Lux operon inserted *S.aureus* and *P. aeruginosa* are monitored real time with the help of an imaging system. Also a multi photon laser scanning microscopy can be used for the detection of biofilm formation in fluorescent bacteria (50).

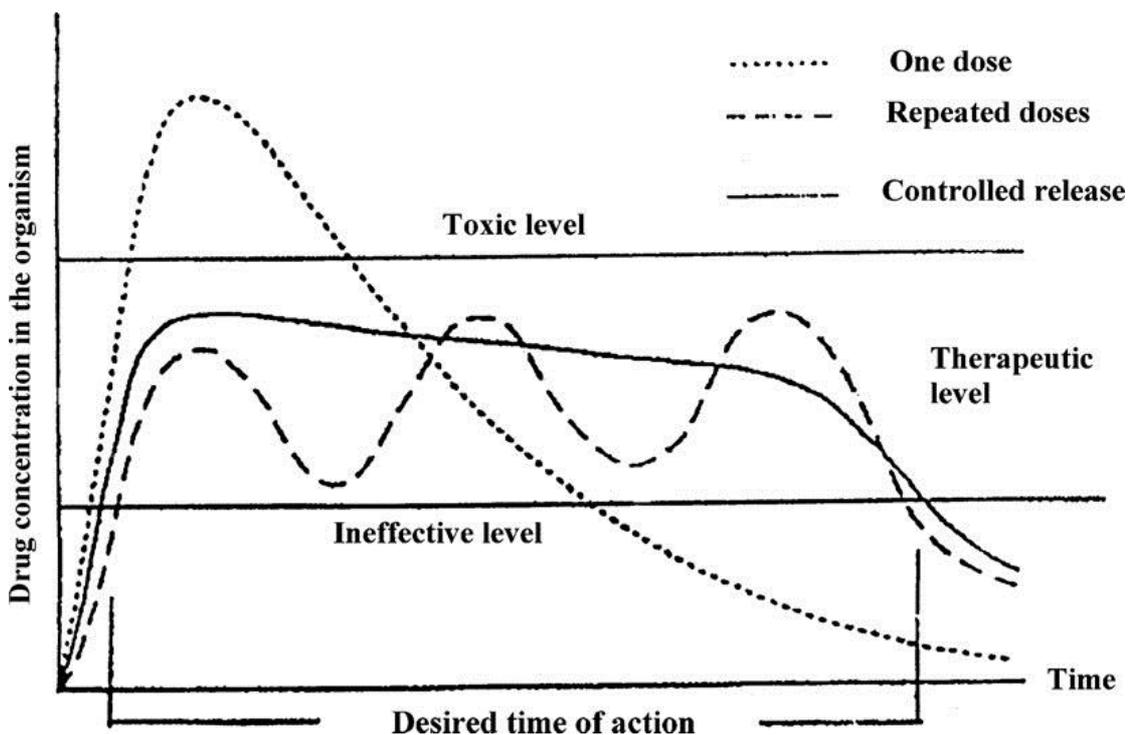

### **2.2.3 Vancomycin**

Vancomycin is a tricyclic glycopeptide antibiotic isolated from *Streptomyces orientalis*, effective against Gram-positive bacteria, especially MRSA (51-53). The drug shows its bactericidal effect by inhibiting the cell wall biosynthesis with binding to the cell wall precursors (54). Vancomycin has side effects such as nephrotoxicity, ototoxicity, poor venous tolerance thus systemic administration of this drug has some limitations (55). Vancomycin has four to six hours *in vivo* half-life and it is extracted from the body by renal extraction. On the other hand, *in vitro* half-life of the drug at 37°C is nine hours (56). The minimum inhibitory concentration (MIC) of vancomycin for MRSA is  $\leq 2 \mu\text{g/ml}$  (57).

### **2.3 Controlled Drug Delivery Systems**

Controlled drug delivery systems gain attention, since the infection in the body cannot be eradicated by systemic or parenteral drug delivery. As the infection deteriorates the blood circulation, systemically delivered drugs cannot reach to infection area. Beside the delivery of the drug to the infection area, these systems also have advantages like improving the efficacy of the drug and diminishing its

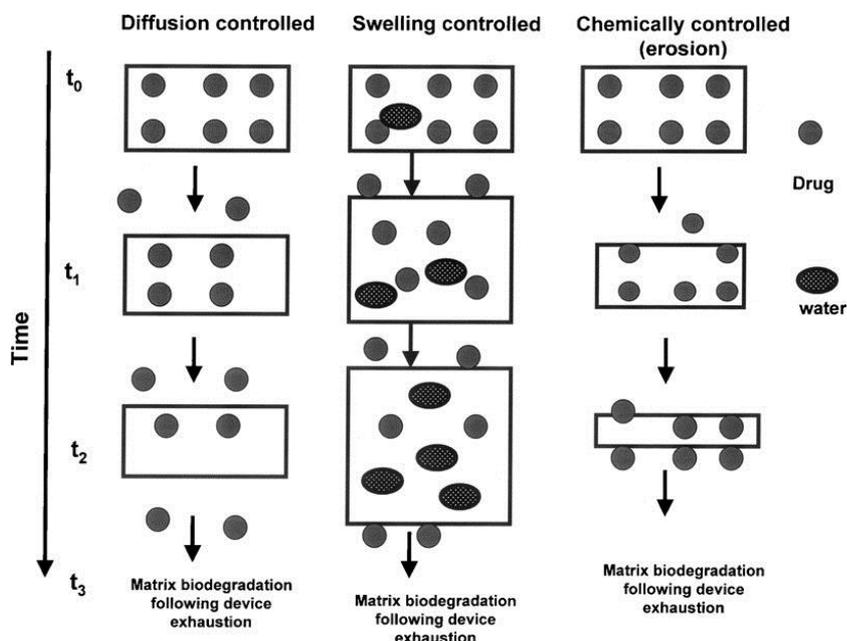

toxic effects (58). In controlled drug release, the drug concentration is in therapeutic level for the desired time of action (Figure 5) (59).

**Figure 5.** The illustration of controlled release (59).

For controlled drug delivery, there must be a carrier for the drug and drug is released either by diffusion, chemical reaction or solvent activation and transport. In diffusion systems, there is either a matrix (monolithic systems) or a reservoir (membrane systems) and drugs are diffused through these systems. In a matrix; drug is uniformly dissolved or dispersed (60) whereas in reservoir systems, drugs are surrounded by the carrier (61).

In chemically controlled drug delivery systems, drug is released by degradation of the carrier material by water or a chemical reaction. Also, the drug can be linked to the carrier material with unstable bonds that can be degrading by water or a chemical reaction and release the drug. In solvent activated mechanism, the drug can be released either by swelling of the carrier material or by osmotic effect in which external water enters the system and gives out the drug (Figure 6) (59).

**Figure 6.** The illustration of three mechanisms for controlled drug delivery (59).

Drug release systems can be classified as nonbiodegradable and biodegradable systems and many different types of carrier materials like polymers, ceramics and polymer/ceramic composites can be used in their fabrication.

## 2.4 Polymers

Polymers are the macromolecules that are made up of the repeating units of monomers. Polymers are classified as natural and synthetic polymers, and they are widely used as surgical sutures, implants, and drug delivery systems and as scaffolds in tissue engineering. The natural polymers are found and extracted from the nature while synthetic polymers are industrially synthesized (55). Agarose (62), alginate (63), hyaluronic acid (64), chitosan (65), methylcellulose (66), fibrin (67) and collagen (68) are all natural polymers used for these purposes. On the other hand, poly alpha-hydroxy acids, polyhydroxyalkanoate (69), polyacrylate, polycaprolactone (70), polyanhydrides (71), polyorthoester (72), polyvinyl alcohol (73) and polymethylmethacrylate (74) are all synthetic polymers used to manufacture drug release systems, scaffolds and implants.

Polymethylmethacrylate (PMMA) is used as an antibiotic carrier for orthopedic infections since 1970s (75). Unfortunately, PMMA has several drawbacks: PMMA is a nonbiodegradable polymer, so a second surgery is needed for its removal from the body. The polymer shows an exothermic reaction during polymerization, thus only heat stable antibiotics can be carried and the material has a poor elution profile (76, 77). In order to alter these disadvantages, biodegradable biopolymers can be used. Poly alpha-hydroxy acids like polylactic acid (PLA) and polyglycolic acid (PGA) and their copolymers are biodegradable polymers generally used instead of PMMA as a drug carrier.

#### **2.4.1 Poly (D, L-Lactic acid) (PDLA)**

PDLA is a copolymer of PLA, which can be found in two different forms: L-lactide (PLLA) and D-lactide (PDLA). These two forms are in semi crystalline structure. When the racemic mixtures of L-lactide and D-lactide are polymerized, an amorphous poly (D,L-lactide) is formed (78). PDLA is used as a controlled release system carrier and scaffold material due to its biocompatibility and biodegradability (79). During the biodegradation of PDLA, the center is degraded more faster than the outer layer as a result of high levels of acidic degradation products (80).

#### **2.4.2 Poly (D, L-Lactide-co-Glycolic acid) (PLGA)**

Poly (D, L-lactide-co-glycolic acid) is a biodegradable and biocompatible polymer used for various medical purposes, and synthesized by ring opening co-polymerization of D,L-lactide and glycolide. Since the chain compositions determine the degradation rate of the polymer, the glycolic acid found its structure leads the faster degradation of the polymer (55). The degradation rate of PLGA can be adjusted by modifying the lactide:glycolide ratio of the polymer (81). If the lactide ratio is higher than the glycolide ratio, polymer degrades much slower. As an exception, PLGA with 50:50 lactide:glycolide ratio, degrades at a fastest rate (82).

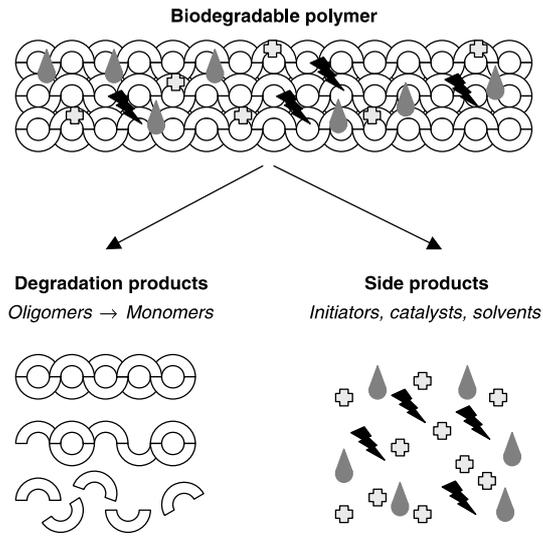

### **2.4.3 Biodegradation of PDLLA and PLGA**

Biodegradation is the biological breakdown of the polymers and changing their physicochemical properties as a result of their interactions with the surrounding environment. The biodegradation rate is based on the molecular weight, surface area, material phase (crystalline versus amorphous) and racemic ratio of the polymer, presence of additives, implantation site and degradation mechanism (83, 84).

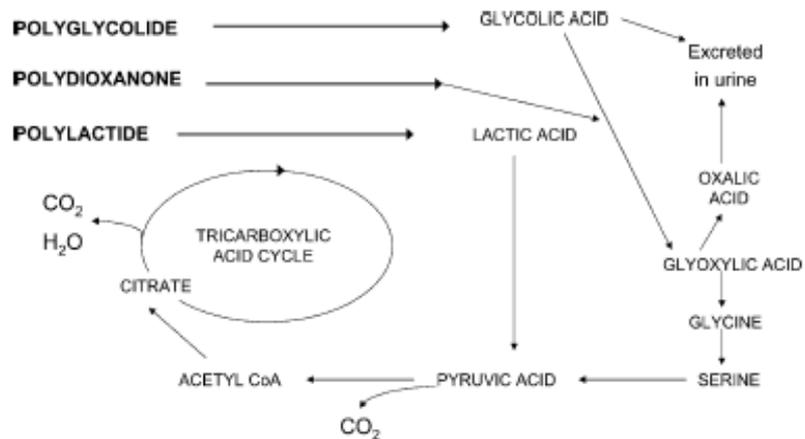

Biodegradation can occur as surface erosion or bulk erosion. In surface erosion, only the surface is degraded while the inner structure is nondegraded. By contrast in bulk erosion, all material is degraded (85).

Polymers can be degraded by hydrolysis, oxidation and enzymatic mechanisms. In hydrolytic degradation, the chemical bonds found in the backbone of the polymer are sheared by the water attack and form monomers. In oxidative degradation, the polymers are generally exposed to body. Since this exposition evokes the immune response, the reactive oxygen species produced by macrophages and leukocytes will sheared the polymer chains and lead the biodegradation of the polymer. In enzymatic degradation, enzyme is diffused to the surface of the polymer and adsorbed by the substrate. After, hydrolytic mechanism is catalyzed and polymer degrades (84).

When a polymer degrades, it also releases some side products, which can induce the local inflammation (Figure 7) (86).

**Figure 7.** Biodegradation of a polymer (86).

**Figure 8.** The metabolic biodegradation of PDLLA and PLGA (87).

In the biodegradation of PDLLA and PLGA polymers, their ester bonds are cleaved by hydrolysis. As a result of the degradation, lactic acid and glycolic acid monomers come off and in *in vivo* conditions, these monomers enter the tricarboxylic acid cycle and excreted from the respiratory system as water and carbon dioxide (Figure 8) (86, 87). The lactic acid and glycolic acid monomers also trigger the further degradation since the acidic products lower the pH of the solution (55).

## **2.5 Bioceramics**

Bioceramics are widely used as implant materials and drug carriers especially in the orthopedics. As they can restore the functions of teeth and bone, they are also used as bone fillers since 1960s (88). There are various types of bioceramics used in medical field like calcium phosphates such as hydroxyapatite (89) , beta-tricalcium phosphate (90), biphasic calcium phosphate (91) ; (92) calcium sulphate; and bioactive glasses (93).

### **2.5.1 Beta-Tricalcium Phosphate ( $\beta$ -TCP)**

Beta-tricalcium phosphate ( $\text{Ca}_3(\text{PO}_4)_2$ ) is the beta ( $\beta$ ) polymorph of tricalcium phosphate known as a biodegradable ceramic (94). Besides biodegradability,  $\beta$ -TCP also has osseointegration, osseoconduction and bioactivity properties (95).  $\beta$ -TCP is more soluble than hydroxyapatite but its resorption rate is not high enough for complete osseointegration (52).

## **2.6 Research Questions**

We asked whether;

Vancomycin containing PDLLA or PLGA/ $\beta$ -TCP composites can be developed and characterized.

These composites will release vancomycin for six weeks while showing antibacterial activity against MRSA and inhibit biofilm formation.

These composites will allow cell proliferation and differentiation and stimulate osteogenesis related signaling molecules.

## **2.7 Hypotheses**

The hypotheses of the study were:

Vancomycin will be released from vancomycin containing PDLLA/ $\beta$ -TCP and vancomycin containing PLGA/ $\beta$ -TCP composites for six weeks and will have antibacterial activity against MRSA and inhibit biofilm formation.

The vancomycin containing PDLLA/ $\beta$ -TCP and vancomycin containing PLGA/ $\beta$ -TCP composites will proliferate and differentiate mesenchymal stem cells in *in vitro* conditions and stimulate osteogenesis related signalling molecules.

## **2.8 Aims of Study**

The aims of the study are;

- 1) to develop and characterize vancomycin containing PDLLA/ $\beta$ -TCP and vancomycin containing PLGA/ $\beta$ -TCP composites
- 2) These composites will release vancomycin for six weeks, having antibacterial activity against MRSA and inhibit biofilm formation
- 3) These composites will be biocompatible with mesenchymal stem cells in *in vitro* conditions.

## **2.9 Study Design**

This study was done to search (a) the biofilm inhibition potential of vancomycin containing PLGA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites in *in vitro* conditions and (b) the biocompatibility of vancomycin containing PLGA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites with mesenchymal stem cells. At the beginning, the composites were fabricated and characterized. Later, the *in vitro* degradation of the composites was analyzed. This was followed with the analysis of bone like apatite formation on the surface of the composites. Also, vancomycin releases from the composites were observed for six weeks. Further, microbiological studies were conducted for antibiotic susceptibility and biofilm formation. At the end, cell culture studies were done with respect to the biocompatibility of the composites.

## CHAPTER 3

### EXPERIMENTAL

#### 3.1 Materials

PLGA (Resomer RG858S) and PDLLA (Resomer R202S) were purchased from Evonik Industries (Evonik Industries, Essen, Germany). These were both solid polymers with white to off white colour. PLGA composed of 85% D,L-lactide and 15% glycolide according to its molar ratio. PLGA and PDLLA had 1.4 dl/g and 0.22 dl/g inherent viscosity, respectively. Vancomycin hydrochloride was purchased from Zhejiang Medicine (Zhejiang Medicine Co.,Ltd, Xinchang Pharmaceutical Factory, Zhejiang, China). It was an almost white, hygroscopic powder, which was freely soluble in water and slightly soluble in 96% ethanol. Beta tricalcium phosphate ( $\beta$ -TCP) was purchased from BMT Calsis (BMT Calsis Health Technologies Co., Ankara, Turkey). It was a white powder with 75-200  $\mu\text{m}$  particle size. Dichloromethane ( $\text{CH}_2\text{Cl}_2$ ) (JT Baker, Avantor Performance Materials, Pennsylvania, United States of America) was used to dissolve the polymers.

#### 3.2 Preparation of Vancomycin containing Polymer/Bioceramic Composites

In order to prepare vancomycin containing PLGA/ $\beta$ -TCP composites, a total of 8574 mg of PLGA was dissolved in 40 ml of dichloromethane. After, 5355 mg of vancomycin hydrochloride powder was added into the solution followed by the addition of 16071 mg  $\beta$ -TCP. The mixture was stirred on a magnetic stirrer with a closed lid and dried at room temperature for 24 hours. After the evaporation of dichloromethane, the rest powdery structure was grinded in a porcelain mortar. For vancomycin containing PDLLA/ $\beta$ -TCP composites, all the procedures mentioned

above were repeated but this time 8574 mg of PDLLA was used instead of PLGA. The powders were hand pressed in a tablet pressing machine and totally 149 vancomycin containing PLGA/ $\beta$ -TCP composite discs and 160 vancomycin containing PDLLA/ $\beta$ -TCP composite discs were obtained. The composite discs had 3 mm height with 6 mm diameter. The final content ratios of the composites were 53.57%  $\beta$ -TCP, 28.58% polymer and 17.85% vancomycin hydrochloride.

### **3.3 Characterization of Vancomycin containing Polymer/Bioceramic Composites**

#### **3.1.1 Scanning Electron Microscopy**

Surface topography of the vancomycin containing PLGA/ $\beta$ -TCP and PDLLA/ $\beta$ -TCP composite discs were analyzed by using Nova Nanosem 430 (Fei, Oregon, USA) Scanning Electron Microscope in METU Metallurgical and Materials Engineering Department. The images were taken at 500, 1000 and 2500 magnifications. The composite discs were fixed on supports and coated with gold film to obtain a conducting surface before the analysis. The surface composition of the composite discs was also analyzed with a built-in X-ray energy-dispersive spectrometry (EDS).

#### **3.1.2 Fourier Transform Infrared Spectroscopy**

The vancomycin containing composite discs were evaluated by using fourier transformed infrared microscopy (FTIR-ATR) (Bruker Alpha, Bruker, Massachusetts, United States of America). PLGA, PDLLA,  $\beta$ -TCP and vancomycin were also analyzed to determine the similarities and differences between the composite discs and plain materials. The infrared spectrum was collected in the range of 4000–400 $\text{cm}^{-1}$  with a resolution of 4 $\text{cm}^{-1}$  and scans of 24.

### **3.4 *In vitro* Degradation of Vancomycin containing Polymer/Bioceramic Composites**

The vancomycin containing composite discs from each group were immersed into simulated body fluid (SBF) for *in vitro* degradation. SBF was prepared as follows:

sterilized polyethylene bottle was filled with 750 ml of ultra pure water. A magnetic stirring bar was placed into the bottle and the water was heated up to 37°C on a magnetic stirrer. Afterwards, 7996 mg of sodium chloride (NaCl, Merck, New Jersey, United States of America), 350 mg of sodium bicarbonate (NaHCO<sub>3</sub>, Merck, New Jersey, United States of America), 224 mg of potassium chloride (KCl, Horasan Chemistry, Ankara, Turkey), 228 mg of potassium phosphate dibasic trihydrate (K<sub>2</sub>HPO<sub>4</sub>·3H<sub>2</sub>O, Sigma Aldrich, Missouri, United States of America), 305 mg of magnesium chloride hexa hydrate (MgCl<sub>2</sub>·6H<sub>2</sub>O, Riedel-de Haenn AG, Hanover, Germany), 40 ml 1M hydrogen chloride (HCl, Sigma Aldrich, Missouri, United States of America), 278 mg of calcium chloride (CaCl<sub>2</sub>, Sigma Aldrich, Missouri, United States of America), 71 mg of sodium sulphate (Na<sub>2</sub>SO<sub>4</sub>, Sigma Aldrich, Missouri, United States of America) and 6057 mg of tris-(hydromethyl) aminomethane ((CH<sub>2</sub>OH)<sub>3</sub>CNH<sub>2</sub>, Sigma Aldrich, Missouri, United States of America donated from Hacettepe University Faculty of Pharmacy) were added, respectively. pH of the solution was set to 7.4 by adding 1 kmol/dm<sup>3</sup> of HCl solution. Later, the volume was completed to 1000 ml by adding ultra pure water (96).

In vitro degradation of the composite discs were analyzed for 1 week, 3 weeks and 6 weeks. For each time point vancomycin containing composite discs from each group (n=3) were weighted and placed into polystyrene bottles filled with 10 ml of SBF. At the predetermined time points, the composite discs were removed from the bottles; excess solution was removed with a filter paper and weighted. The wet composite discs were dried under a laminar flow for 24 h and dry discs were weighted. The mass loss of the composite discs were determined by the following equation where  $m_i$  is the initial dry weight of the composite disc and  $m_f$  is the final dry weight of the composite disc.

$$\text{mass loss (\%)} = \frac{m_i - m_f}{m_i} \times 100\%$$

For water uptake calculation, percent of absorbed SBF was determined like mass loss equation. This time, initial dry weight of the composite disc was subtracted from wet

weight of the composite disc and divided with initial dry weight of the composite disc. The result was multiplied with hundred to obtain the percentage.

### **3.5 Bone Like Apatite Formation on the Surface of Vancomycin containing Polymer/Bioceramic Composites**

Apatite formation on the surface of the composite discs that were immersed into SBF solution for 1, 3 and 6 weeks were determined with Nova Nanosem 450 (Fei, Oregon, USA) Scanning Electron Microscope. The elemental compositions of the composite discs were analyzed with EDS and the discs FTIR spectra were obtained.

### **3.6 Vancomycin Release Study for Vancomycin containing Polymer/Bioceramic Composites**

Vancomycin containing composite discs from each group (n=6) were immersed into 50 ml phosphate buffered saline (PBS) containing polystyrene tubes. PBS was prepared by dissolving one PBS tablet (Oxoid, Hampshire, United Kingdom) in 100 ml distilled water. The tubes were placed into a hot water bath at 37°C and shaken constantly at 30 rpm. At predetermined time points (1, 2, 4, 8, 12, 24, 48, 120 h and 1, 2, 3, 4, 5, 6 weeks) 1 ml PBS was withdrawn and replaced with equal amount of fresh PBS. The withdrawn solutions were analyzed spectrophotometrically with Nanodrop ND 1000 spectrophotometer (Thermo Scientific, Massachusetts, United States of America) at 280 nm with 1:10 dilution factor. A calibration curve for vancomycin was generated to calculate the amount of released vancomycin in the solution.

The validation of spectrophotometer analysis was done by measuring three different vancomycin concentrations (100 µg/ml, 200 µg/ml and 300 µg/ml) at three different time points for six times.

### **3.7 Content Uniformity of Vancomycin containing Polymer/Bioceramic Composites**

In order to determine the vancomycin stability in the composite discs, the discs were weighted and dissolved in 30 ml of dichloromethane. Later, 15 ml PBS was added and the mixture was vortexed for 10 min followed with 1 h of stirring. The supernatant was separated by centrifugation at 1500 rpm for 5 min. The solution was analyzed spectrophotometrically with Nanodrop ND 1000 spectrophotometer (Thermo Scientific, Massachusetts, United States of America) at 280 nm with 1:100 dilution factor.

### **3.8 Microbiological Studies of Vancomycin containing Polymer/Bioceramic Composites**

#### **3.8.1 Antibiotic Susceptibility Test for Vancomycin containing Polymer/Bioceramic Composites**

The microbiological effects of the vancomycin containing composite discs were evaluated with antibiotic susceptibility test. Slime forming and slime non-forming methicillin resistant *Staphylococcus aureus* (MRSA) strains were obtained from Hacettepe University Faculty of Medicine Department of Clinical Microbiology. Bacterial suspensions were pipetted into sterile glass tubes containing 2 ml of trypticase soy broth (Becton Dickinson, New Jersey, United States of America) and the bacterial cultures were set to 0.5 McFarland standard with a benchtop turbidity meter (Grant Instruments, Cambridge, United Kingdom). Sterile tampon swabs (LP Italiana Spa, Milano, Italy) were dipped into bacterial cultures and streaked to sterile 90 mm Mueller Hinton agar plates (Orbak, Çağdaş Health Services, Ankara, Turkey). A single vancomycin containing composite disc from each group (n=3) were placed into the middle of the agar plate and the plate was incubated at 37°C overnight. The bacterial cultures were passaged in new sterile glass tubes containing fresh 2 ml trypticase soy broth by setting the fresh bacterial solution to 0.5 McFarland standard. The zone of inhibitions were measured and recorded. The fresh bacterial cultures were again streaked to fresh sterile agar plates like the day before and the composite discs were removed from the old plates and placed to new agar plates. The entire assay was done under aseptic conditions and lasted for 21 days.

### **3.8.2 Biofilm Inhibition Study for Vancomycin containing Polymer/Bioceramic Composites**

Biofilm inhibition capabilities of vancomycin containing composites discs were evaluated with tissue culture plate method. A vancomycin containing composite disc from each group (n=3) was put into a polystyrene tube containing 10 ml of SBF and placed in a hot water bath at 37°C and shaken constantly at 30 rpm. Every week, 1 ml SBF was withdrawn and replaced with equal amount of fresh SBF until week 6. Beside SBF release mediums, PBS release mediums were also used for the assay. Each time point was carried out in triplicate. Only slime forming MRSA strain was used for this study. 200 µl bacteria was inoculated to fresh 2 ml trypticase soy broth and incubated at 37°C overnight. On the other day, bacteria suspension turbidity was checked with a benchtop turbidity meter and the bacteria suspension with 11.0 turbidity was poured into fresh 48 ml trypticase soy broth. This process was done in duplicate. 200 µl bacterial culture was added into each well of round bottom 96 well plates and 20 µl of drug release mediums collected from release studies were added to the wells. The plates were incubated at 37°C for 48 h. Trypticase soy broth without any bacteria was used as negative control while bacterial culture without any release medium was used as positive control.

After incubation, tissue culture plates were turned upside down and the planktonic bacteria were poured out. The plates were washed three times with tap water (200 µl water for each well). After washing, 125 µl 0.1% crystal violet stain was added to each well and plates were incubated at room temperature for 10 min. The plates were shaken and the excess stain was poured out, again the wells were washed twice with water. The plates were placed onto paper towel and allowed to dry. Each well was filled with 200 µl 95% ethanol and the plates were incubated at room temperature with closed lids for 15 min. The wells were gently mixed with pipetting and 125 µl ethanol-crystal violet mix from each well were placed into a new 96 well plate. The new plates were spectrophotometrically analyzed in ELISA reader (Tecan Sunrise, Mannedorf, Switzerland) at 620 nm.

### **3.9 Cell Culture Studies of Vancomycin containing Polymer/Bioceramic Composites**

Two different vancomycin containing composite discs were evaluated for their proliferation and osteogenic potential. Cell proliferation and alkaline phosphatase activities of the composite discs were done with both human bone marrow originated mesenchymal stem cells (MSC, passage 6) (Poietics PT 2501, Lonza, Basel, Switzerland) and SaOS-2 osteosarcoma cells (passage 17) (Sigma Aldrich, Missouri, United States of America). Both cell cryovials were thawed in 37°C water and the cells were transferred into polypropylene tubes with 2 ml PBS. Empty cryovials were washed with 4 ml PBS and the PBS was added to the polypropylene tube. The PBS amount in the propylene tube was completed to ten milliliters. The tubes were centrifuged at 1500 rpm for 5 min and supernatant was poured. 5 ml PBS was added to each tube and the cell pellet was dispersed. 50 µl cell suspension was mixed with 50 µl trypan blue (Biological Industries, Israel) in a centrifuge tube and the cells were counted on a Burker lamina.

For cell proliferation assay, total 202500 MSC and 202500 SaOS-2 cells were used. The assay was done in 24 well cell culture plates (Corning Costar, New York, Unites States of America) for three different time points (1, 3 and 7 days) in triplicate. In a 24 well cell culture plate, 12 wells were used for MSC while the other 12 wells were used for SaOS-2 cells. 7500 cells were seeded on each composite discs and control wells. The cells were cultured with MSC or SaOS-2 medium according to cell type. MSC culture medium consisted of 52.8% Dulbecco's Modified Eagle Medium (DMEM) with 1 g/l glucose (Lonza, Basel, Switzerland), 35.2% MCDB-201 medium (Sigma Aldrich, Missouri, United States of America), 10% heat inactivated fetal bovine serum (FBS) (Sigma Aldrich, Missouri, United States of America), 1% penicillin/streptomycin solution (Biochrom AG, Berlin, Germany) and 1% L- glutamine (Biochrom AG, Berlin, Germany) while SaOS-2 culture medium consisted of 89% DMEM with 4.5 g/l glucose (Sigma Aldrich, Missouri, United States of America), 10% heat inactivated FBS and 1% penicillin/streptomycin solution. In every 3-4 days, the mediums were changed. The plates were incubated at 37°C with relative humidity under an atmosphere of 5% CO<sub>2</sub>. At predetermined time points, the

culture mediums were aspirated and 500  $\mu$ l fresh mediums were added with 50  $\mu$ l of cell proliferation agent WST-1 (Roche, Basel, Switzerland) for each well. The plates were incubated at 37°C with relative humidity under an atmosphere of 5% CO<sub>2</sub> for 4 hours. After incubation, 110  $\mu$ l WST-1 containing culture medium was pipetted into a flat bottom 96 well plate and the absorbance of the wells were measured in ELISA reader (Tecan Sunrise, Mannedorf, Switzerland) at 450 nm with 620 nm reference wavelength.

The osteogenic potential of the vancomycin containing composite discs were evaluated with alkaline phosphatase activity staining for both MSC and SaOS-2 cells. 7500 cells were seeded on each composite discs and control wells. The cells were cultured with proper medium for 21 days at 37°C with relative humidity under an atmosphere of 5% CO<sub>2</sub> and in every 3-4 days the mediums were refreshed. On day 21, the mediums were discarded and 400  $\mu$ l Alkaline Phosphate Yellow Liquid substrate system for ELISA (Sigma Aldrich, Missouri, United States of America) was added to each well. The plate was incubated for 30 min, and 100  $\mu$ l of 3 N sodium hydroxide (NaOH) was added to each well to stop the reaction. 200  $\mu$ l final product was pipetted to a flat bottom 96 well plate and analyzed with ELISA reader (Tecan Sunrise, Mannedorf, Switzerland) at 405 nm wavelength.

### **3.10 Real Time Quantitative Polymerase Chain Reaction (RT-qPCR) Assay for Vancomycin containing Polymer/Bioceramic Composites**

Human bone marrow originated MSCs (passage 6, total 1500000 cells) were cultured in T75 flasks with MSC medium at 37°C with relative humidity under an atmosphere of 5% CO<sub>2</sub> and in every 3-4 days the mediums were refreshed. When cell were reached to 60-70% confluency, culture mediums in three flasks were discarded and replaced with osteogenic differentiation medium consisted of %10 FBS, 100 nM dexamethasone, 10 mM  $\beta$ -glycerophosphate (Applichem, Germany) and 0,2 mM L-ascorbic acid (Sigma Aldrich, Missouri, United States of America) in DMEM-LG. Another three flasks mediums were refreshed with MSC medium and these flasks were used as control. Rest of the flasks were used for two different composite discs and extraction mediums were used for this purpose. Briefly, 33 composite discs from

each group were incubated with 30 ml of MSC culture medium. After 14 days of incubation, the cells were trypsinized with 0.25% Trypsin-EDTA (Invitrogen, Gibco, United Kingdom) and suspended in 200  $\mu$ l PBS.

mRNA was isolated with High Pure RNA Isolation Kit (Roche, Basel, Switzerland). 400  $\mu$ l lysis/-binding buffer was added to suspended cells and vortexed for 15 s. The sample was pipetted into a filter tube inserted in a collection tube and the entire tube was centrifuged at 8000 x g for 15 s. After centrifugation, the liquid in the collection tube was discarded. On the other hand, 90  $\mu$ l DNase incubation buffer was mixed with 10  $\mu$ l DNase I and pipetted to the upper reservoir of the filter tube. The entire tube was incubated at room temperature for 15 min. 500  $\mu$ l wash buffer I was added to filter tube and the entire tube was centrifuged at 8000 x g for 15 s. The liquid in the collection tube was discarded again and this time 200  $\mu$ l wash buffer II was added to the filter tube and the entire tube was centrifuged at 13000 x g for 2 min. The filter tube was removed from collection tube and inserted into a sterile microcentrifuge tube. 60  $\mu$ l elution buffer was added to the filter tube and centrifuged at 8000 x g for 1 min. Eluted mRNA in the microcentrifuge tube was analyzed for its concentration and quality with Alphaspec spectrophotometer and stored at -80°C for later analysis.

Complementary DNA (cDNA) was synthesized with Transcriptor High Fidelity cDNA Synthesis kit (Roche, Basel, Switzerland). Total RNA was mixed with 2  $\mu$ l Random Hexamer Primer and PCR-grade water to make 11.4  $\mu$ l total volume. The tube was incubated at 65°C for 10 min in Geneamp 9700 Classic PCR machine (Applied Biosystems, Thermo Scientific, Massachusetts, United States of America) and immediately cooled on ice. Later, 4  $\mu$ l transcriptor High Fidelity Reverse Transcriptase Reaction Buffer, 0.5  $\mu$ l Protector RNase inhibitor, 2  $\mu$ l Deoxynucleotide mix, 1  $\mu$ l DTT and finally 1.1  $\mu$ l Transcriptor High Fidelity Reverse Transcriptase was added to tube to make a 20  $\mu$ l final volume. The reagents were mixed carefully and the tube was incubated at 29°C for 10 min and then incubated at 48°C for 60 min. Finally, reverse transcriptase was inactivated by heating the tube at 85°C for 5 min. The reaction was stopped by placing the tube on ice and cDNA was stored at -20°C.

Real time quantitative PCR analysis was done by using Lightcycler 480 Probes Master Mix (Roche, Basel, Switzerland). 10  $\mu$ l Probes Master was mixed with 5  $\mu$ l PCR grade water. 15  $\mu$ l PCR mix and 5  $\mu$ l cDNA were pipetted into each well of custom plate designed for 86 different genes. The list of the genes and their forward and reverse primer sequences were given in Appendix C. Final PCR reaction was done in Lightcycler 480 with 1 cycle of preincubation (95°C, 10 min), 45 cycles of amplification (95°C, 10 s; 60°C, 30 s; 72°C, 1s) and cooling (40°C, 30 s). Lightcycler 480 software was used to calculate the crossing point (Cp) for target and reference genes with Advance Relative Quantification method. All target genes were normalized to housekeeping genes ACTB, GAPDH and G6PD. The results were given as fold change corresponding to mesenchymal stem cells control group according to  $\Delta\Delta$ Ct calculation.

### **3.11 Statistical Analysis**

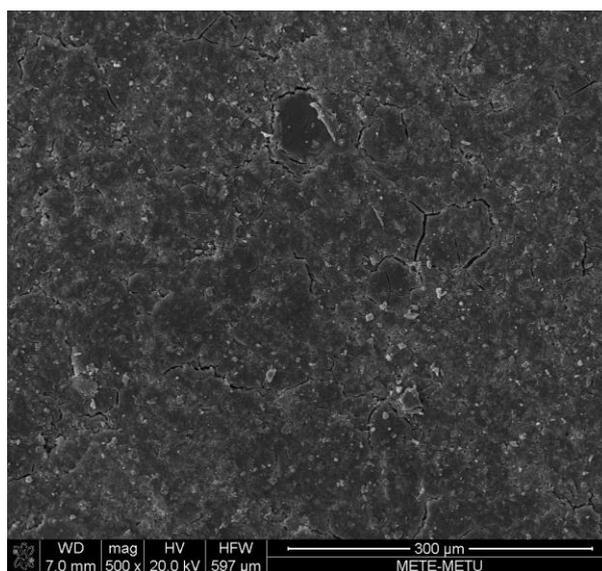

All the results were given in average  $\pm$  standard deviation and analyzed with SPSS 11.0 and StatPlus software. Statistically significant values were defined as  $p < 0.05$  based on Analysis of Variance (ANOVA). For the analysis of RT-PCR study, binary logarithm of the  $\Delta\Delta$ Ct values were obtained and  $\pm 2$  fold changes were assigned as significant.

## CHAPTER 4

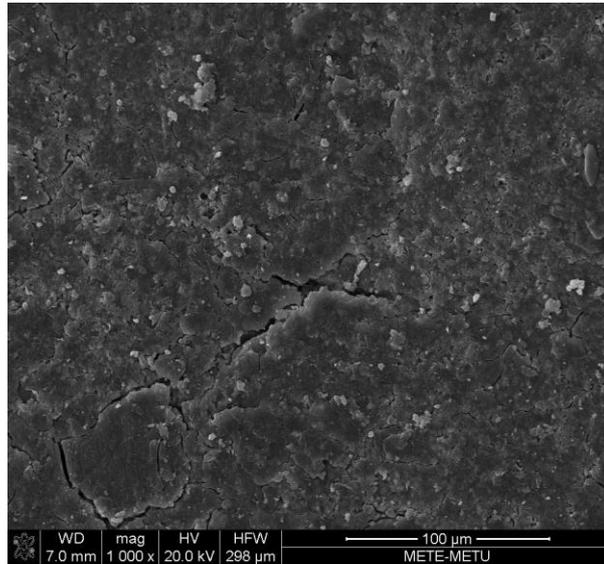

### RESULTS

#### 4.1 Characterization of Vancomycin containing Polymer/Bioceramic Composites

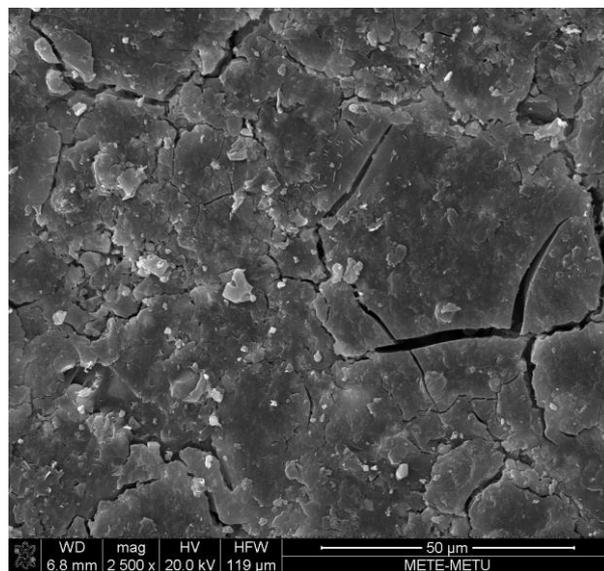

The surfaces of vancomycin containing PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites were analyzed using Nanosem under 500, 1000 and 2500 magnification. SEM micrographs taken from the surfaces of the composites were smooth but micro cracks were noticed as seen in Figure 9 and Figure 10. No notable difference was observed between PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites.

(a)

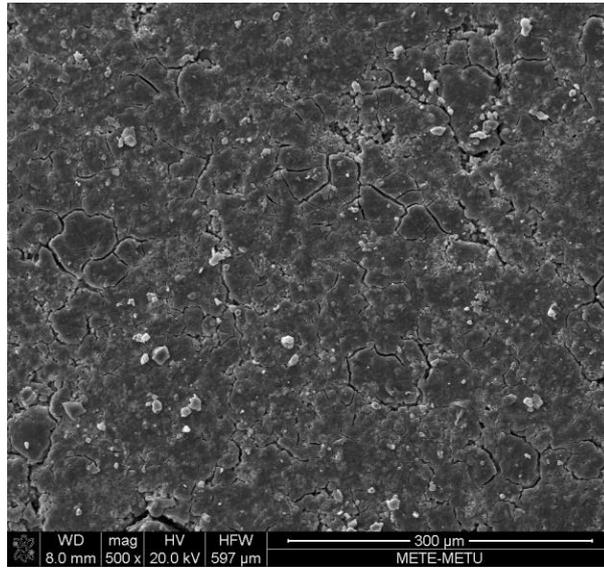

(b)

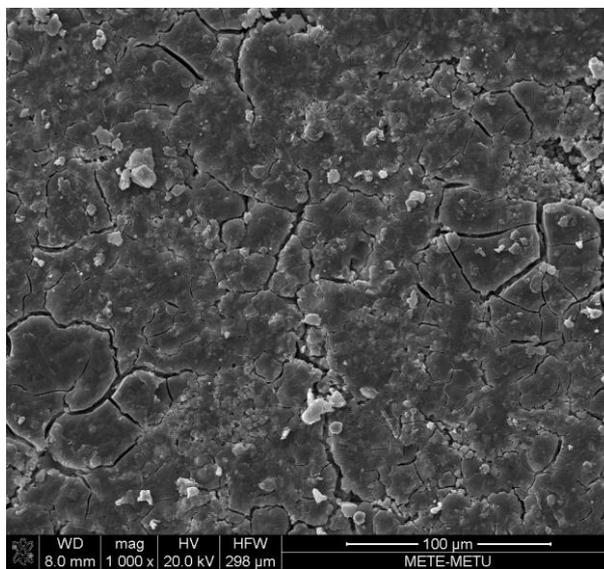

(c)

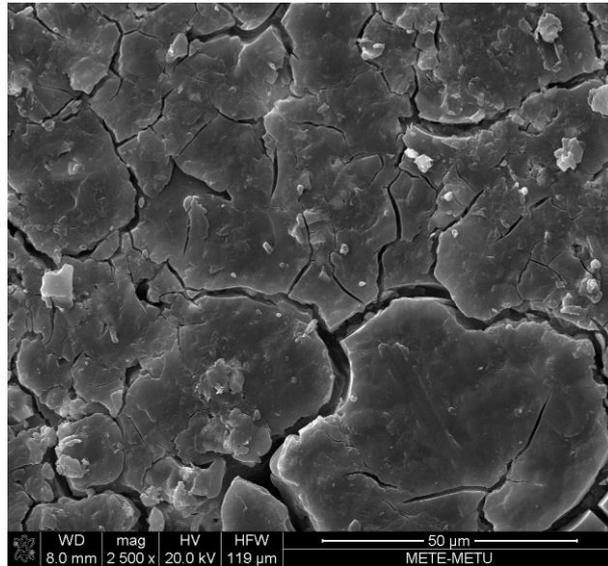

**Figure 9.** SEM micrographs of vancomycin containing PDLLA/ $\beta$ -TCP composites at (a) 500X, (b) 1000X and (c) 2500X magnification.

(a)

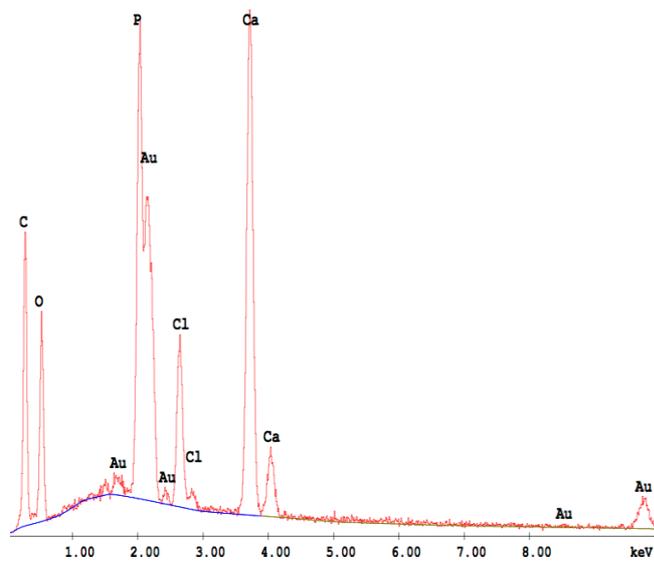

(b)

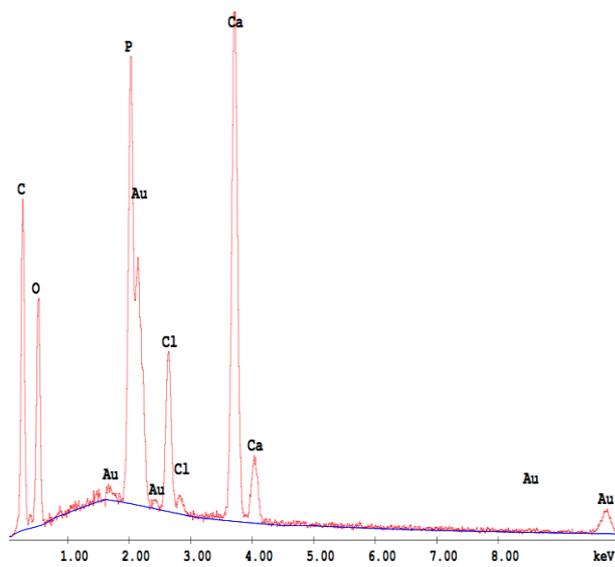

(c)

**Figure 10.** SEM micrographs of vancomycin containing PLGA/ $\beta$ -TCP composites at (a) 500X, (b) 1000X and (c) 2500X magnification.

Vancomycin containing PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites had similar EDS spectra as seen in Figure 11. In both composites, carbon came from polymer, calcium and phosphorous came from tricalcium phosphate and the source of chloride was vancomycin HCl. EDS analysis revealed that, by neglecting carbon, oxygen, and gold, PDLLA/ $\beta$ -TCP composites composed of 28.62% phosphorus, 14.54% chloride, and 56.84% calcium (wt,%), while PDLLA/ $\beta$ -TCP composites composed of 27.43% phosphorus, 14.16% chloride, and 56.41% calcium, respectively (wt,%). These compositions were alike the intended composition where they composed of 53.57% of tricalcium phosphate and 17.85% of vancomycin hydrochloride.

(a)

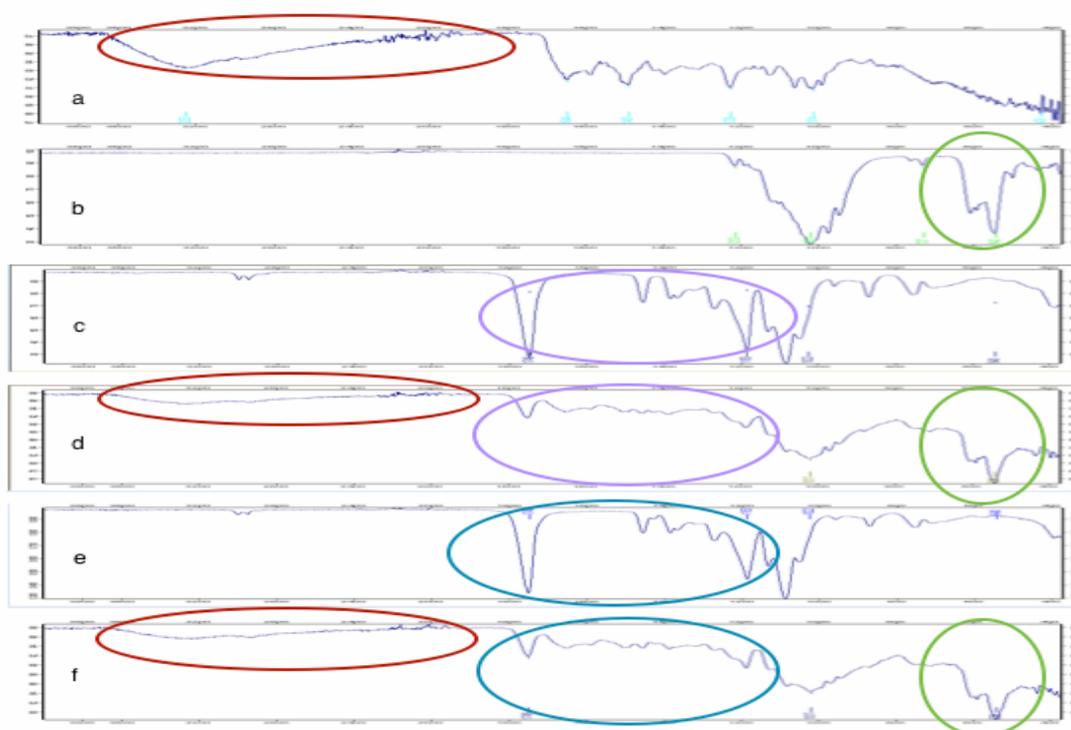

(b)

**Figure 11.** EDS spectra of (a) vancomycin containing PDLLA/ $\beta$ -TCP and (b) PLGA/ $\beta$ -TCP composites.

The FTIR spectra of both composites were shown in Figure 12. The adsorption bands of vancomycin were found at  $3252\text{ cm}^{-1}$ ,  $1644\text{ cm}^{-1}$ ,  $1487\text{ cm}^{-1}$ ,  $1225\text{ cm}^{-1}$ ,  $1014\text{ cm}^{-1}$  and  $426\text{ cm}^{-1}$ . The adsorption band at  $3252\text{ cm}^{-1}$  was for O-H stretching, while  $1644\text{ cm}^{-1}$  showed C=O stretching. The bands at  $1487\text{ cm}^{-1}$ ,  $1225\text{ cm}^{-1}$  pointed C=C band and C-O-C band, respectively (97). The adsorption bands of  $\beta$ -TCP were found at

1212  $\text{cm}^{-1}$  (pyrophosphate CPP group band), 1017  $\text{cm}^{-1}$  (C-O stretching), 727  $\text{cm}^{-1}$  (P-O stretching) and 542  $\text{cm}^{-1}$  (P-O bending) (98). The characteristic peaks of PDLLA and PLGA were found at 1746  $\text{cm}^{-1}$  (C=O band), 1183  $\text{cm}^{-1}$  (C-O band) 1022  $\text{cm}^{-1}$  (C-O band) and 540  $\text{cm}^{-1}$  (C-H band) (99). In both vancomycin containing composites, the peaks were found at 1749  $\text{cm}^{-1}$  (C=O band), 1017  $\text{cm}^{-1}$  (C-O band) and 538  $\text{cm}^{-1}$ . The similarities of spectra were pointed in circles, red defined vancomycin, green defined  $\beta$ -TCP, purple defined PDLLA and blue defined PLGA.

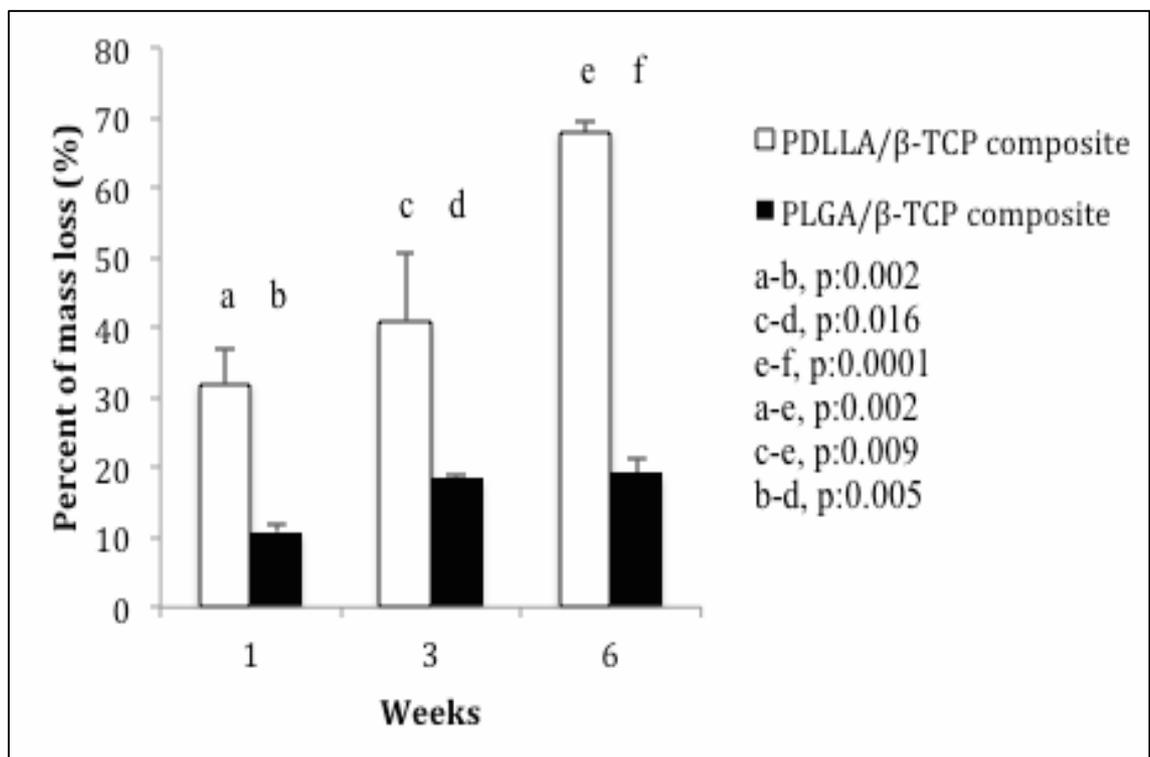

**Figure 12.** FTIR spectra of (a) vancomycin, (b)  $\beta$ -TCP, (c) PDLLA, (d) vancomycin containing PDLLA/ $\beta$ -TCP composite, (e) PLGA and (f) vancomycin containing PLGA/ $\beta$ -TCP composite.

#### 4.2 *In vitro* Degradation of Vancomycin containing Polymer/Bioceramic Composites

The weight loss percentages of vancomycin containing PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites were given in Figure 13. PDLLA/ $\beta$ -TCP composites lost  $31.99 \pm 4.8\%$ ,  $41.01 \pm 9.8\%$  and  $67.98 \pm 1.5\%$  of their mass in week 1, week 3 and week

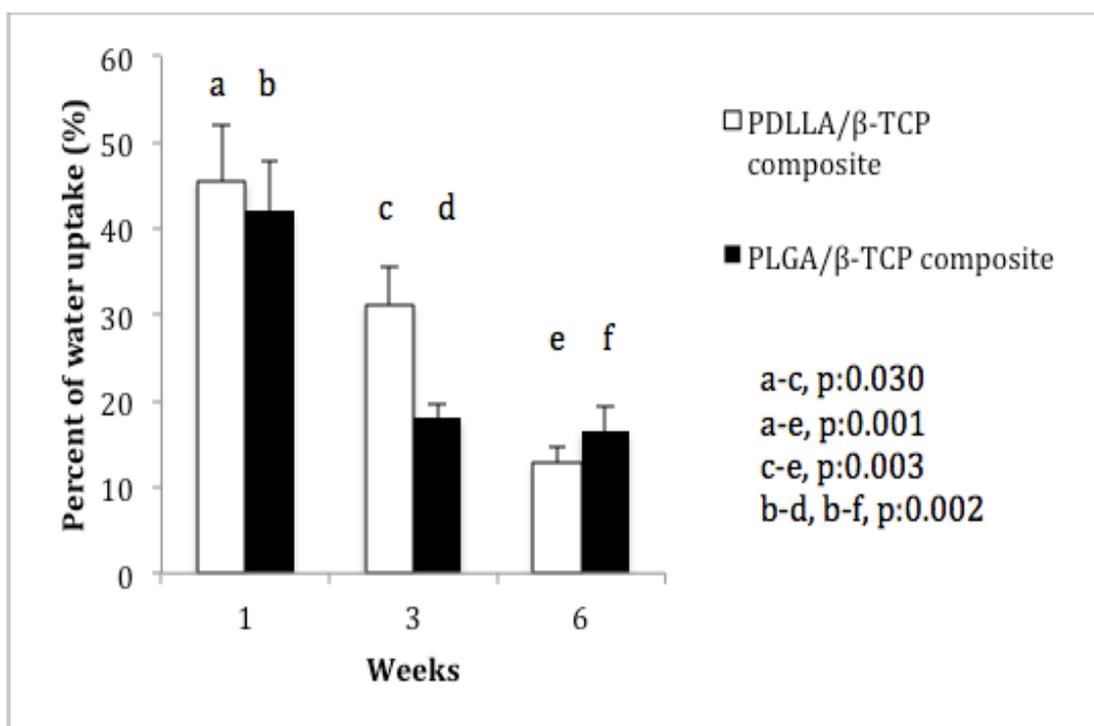

6, respectively. On the other hand, PLGA/ $\beta$ -TCP groups lost only  $10.81\pm 1.1\%$ ,  $18.33\pm 0.6\%$ ,  $19.13\pm 0.2\%$  of their mass in week 1, week 3 and week 6, respectively. The loss percentages rose by time and PDLLA/ $\beta$ -TCP composites lost more mass than PLGA/ $\beta$ -TCP composites. The statistical difference between PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites were  $p: 0.002$  for week 1,  $p: 0.016$  for week 3 and  $p: 0.0001$  for week 6. Also for each group, there was a statistical difference between weeks ( $p: 0.002$  for week 1-week 6 and  $p: 0.009$  for week 3-6 in PDLLA/ $\beta$ -TCP group and  $p: 0.0005$  for week 1-week 3 and  $p: 0.003$  for week 1-week 6 in PLGA/ $\beta$ -TCP group).

**Figure 13.** The mass loss percentages of vancomycin containing composites over six weeks.

The water uptake percentages of vancomycin containing PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites were given in Figure 14. PDLLA/ $\beta$ -TCP composites took  $45.44\pm 6.6\%$ ,  $31.15\pm 4.5\%$  and  $12.75\pm 1.8\%$  water in week 1, week 3 and week 6, respectively. On the other hand, PLGA/ $\beta$ -TCP groups took  $42.02\pm 5.8\%$ ,  $17.98\pm 1.6\%$ ,  $16.47\pm 2.9\%$  water in week 1, week 3 and week 6, respectively. The

percentages decreased by time and there was no statistical difference between PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP groups except week 3 ( $p:0.008$ ). In PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP groups, there was a statistical difference between first and third, first and sixth and third and sixth weeks (For PDLLA/ $\beta$ -TCP, the statistical difference between week 1 and 3 was  $p:0.03$ , between week 1 and 6 was  $p:0.001$  and between week 3 and 6 was  $p:0.003$ . For PLGA/ $\beta$ -TCP, the statistical difference between week 1 and 3, and week 1 and 6 was  $p: 0.002$ ).

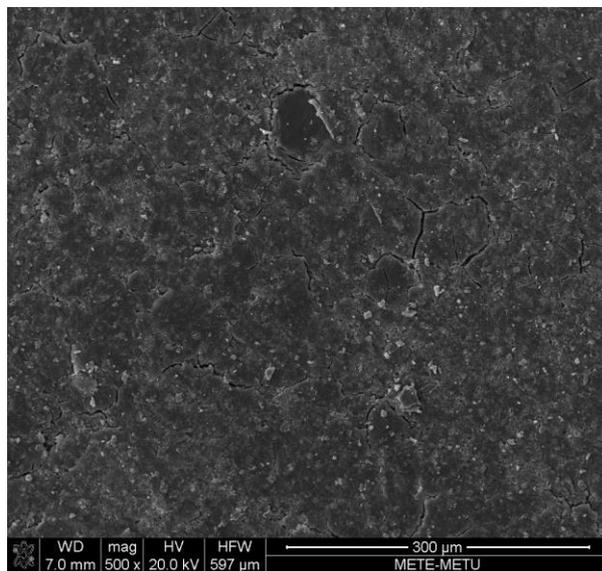

**Figure 14.** The water uptake percentages of vancomycin containing composites over six weeks.

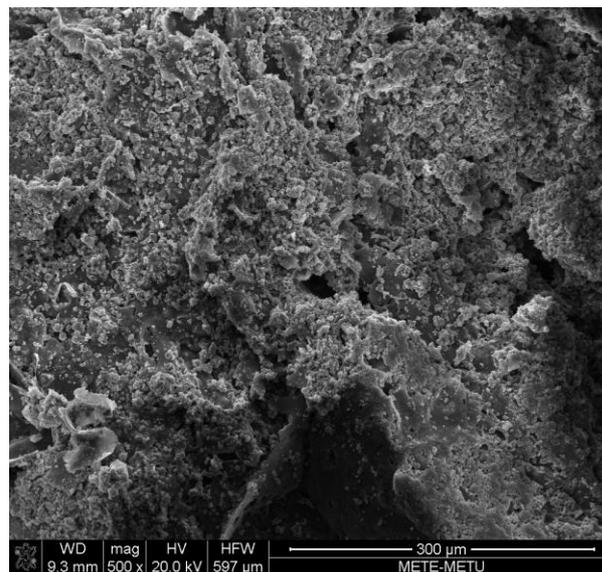

#### **4.3 Bone Like Apatite Formation on the Surface of Vancomycin containing Polymer/Bioceramic Composites**

The apatite formation on the surfaces of vancomycin containing PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites was confirmed with SEM micrographs shown in Figure 15 and Figure 16. With the increase of immersion time, the quantity and size of the precipitates increased. From EDS spectra of the composites, calcium (Ca) and

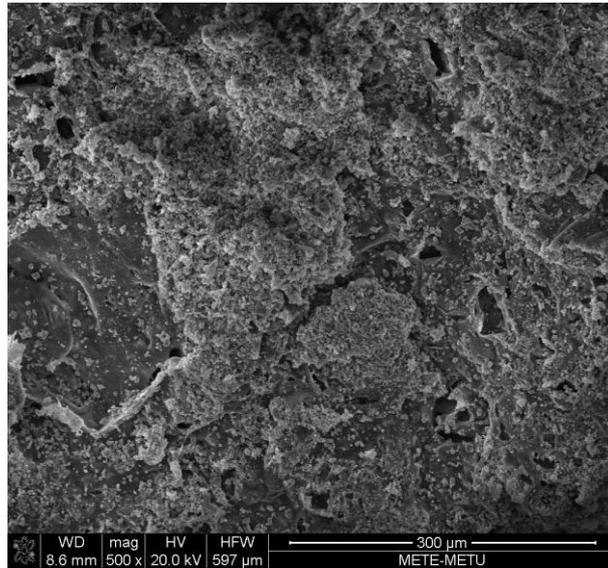

phosphorous (P) molar ratio for each immersion time was calculated. Ca/P molar ratios for PDLLA/ $\beta$ -TCP composites were 1.57, 1.69 and 1.88 for week 1, week 3 and week 6, respectively. Similarly for PLGA/ $\beta$ -TCP composites, Ca/P molar ratios were found 1.66, 1.73 and 1.77 for week 1, week 3 and week 6, respectively. Only week 3 PDLLA/ $\beta$ -TCP and week 1 PLGA/ $\beta$ -TCP composites had similar Ca/P molar ratios like stoichiometric apatite, which is 1.67 while the others were nonstoichiometric apatite.

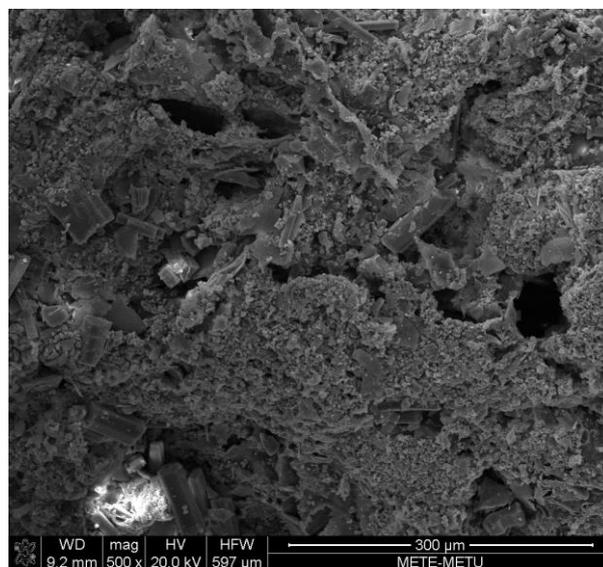

(a)

(b)

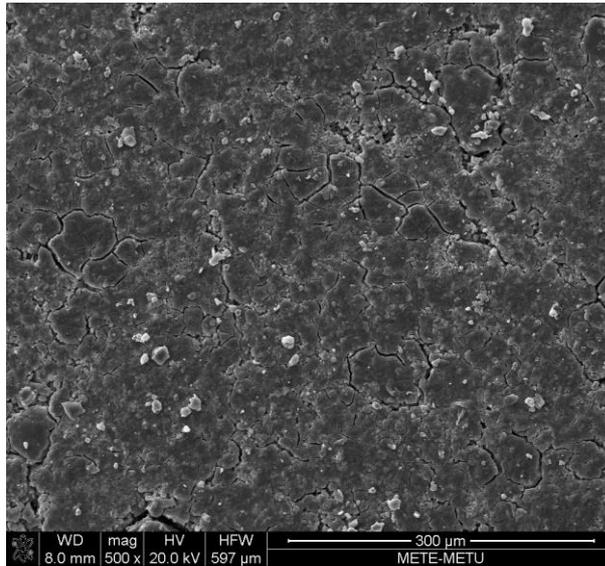

(c)

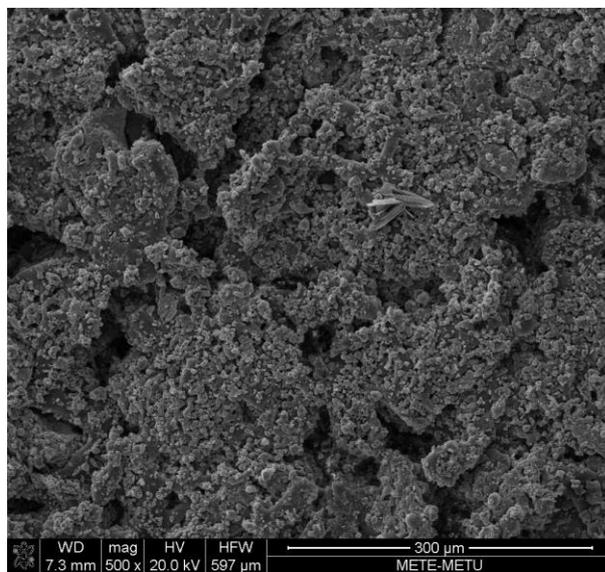

(d)

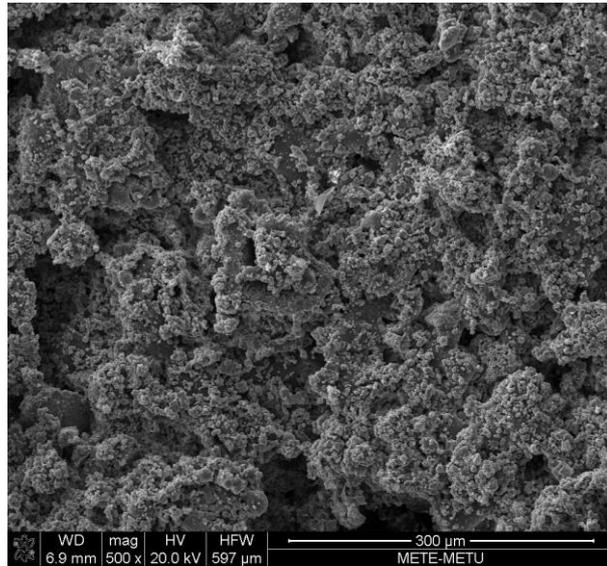

**Figure 15.** SEM micrographs of composites PDLLA/ $\beta$ -TCP for apatite formation: (a) was not immersed into SBF, (b) immersed for 1 week, (c) immersed for 3 weeks, (d) immersed for 6 weeks.

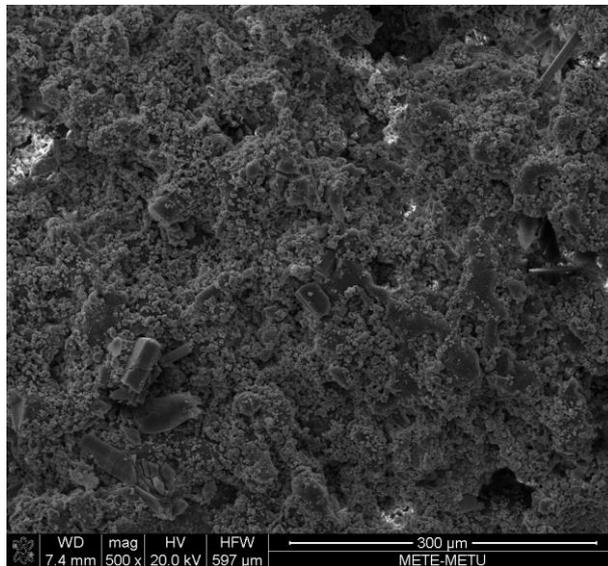

(a)

(b)

(c)

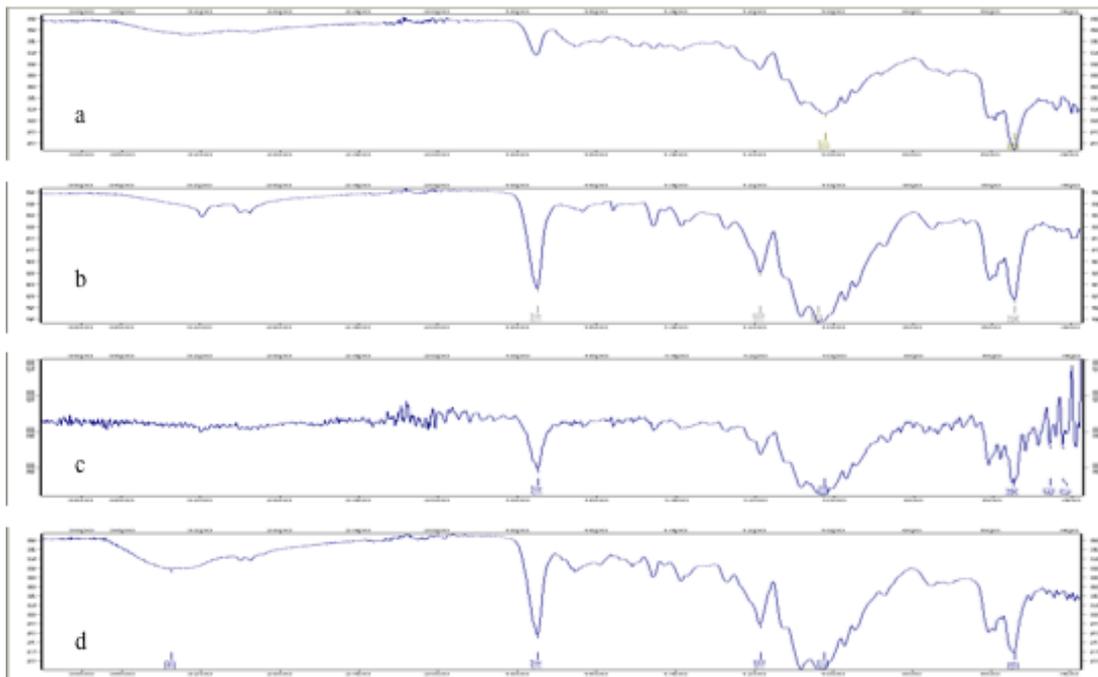

(d)

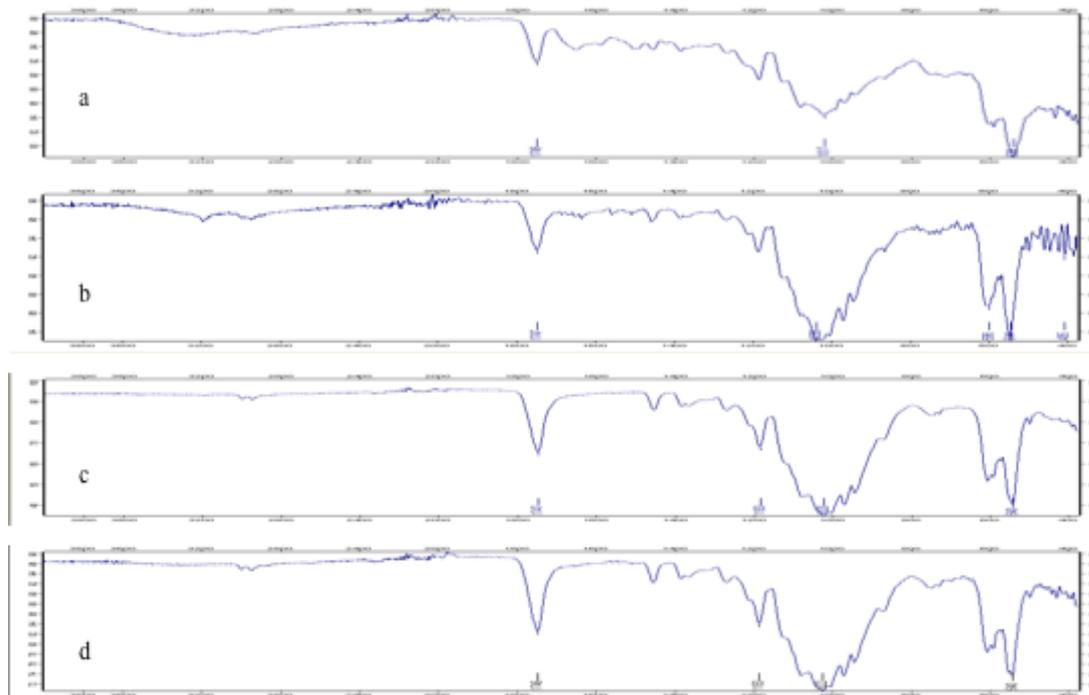

**Figure 16.** SEM micrographs of composites PLGA/ $\beta$ -TCP for apatite formation: (a) was not immersed into SBF, (b) immersed for 1 week, (c) immersed for 3 weeks, (d) immersed for 6 weeks.

Also, FTIR spectra of SBF immersed PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites were obtained and compared with the FTIR spectra of composite that was not immersed into SBF. The spectra of both composites were shown in Figure 17 and 18. The characteristic peaks for PDLLA/ $\beta$ -TCP composite after seven days of SBF immersion were found at  $1747\text{ cm}^{-1}$ ,  $1183\text{ cm}^{-1}$ ,  $1037\text{ cm}^{-1}$  and  $540\text{ cm}^{-1}$ . These peaks

were found at  $1747\text{ cm}^{-1}$ ,  $1024\text{ cm}^{-1}$ ,  $545\text{ cm}^{-1}$ ,  $453\text{ cm}^{-1}$  and  $421\text{ cm}^{-1}$  after three weeks of SBF immersion. After six weeks of SBF immersion, the peaks were found at  $3351\text{ cm}^{-1}$ ,  $1747\text{ cm}^{-1}$ ,  $1183\text{ cm}^{-1}$ ,  $1022\text{ cm}^{-1}$  and  $539\text{ cm}^{-1}$ . Similarly, the characteristic peaks for PLGA/ $\beta$ -TCP composite after a week of SBF immersion were found at  $1747\text{ cm}^{-1}$ ,  $1038\text{ cm}^{-1}$ ,  $598\text{ cm}^{-1}$ ,  $544\text{ cm}^{-1}$  and  $405\text{ cm}^{-1}$ . These peaks were found at  $1747\text{ cm}^{-1}$ ,  $1183\text{ cm}^{-1}$ ,  $1020\text{ cm}^{-1}$  and  $540\text{ cm}^{-1}$  after three weeks of SBF immersion. After six weeks of SBF immersion, the peaks were found at  $1746\text{ cm}^{-1}$ ,  $1183\text{ cm}^{-1}$ ,  $1022\text{ cm}^{-1}$  and  $543\text{ cm}^{-1}$ .

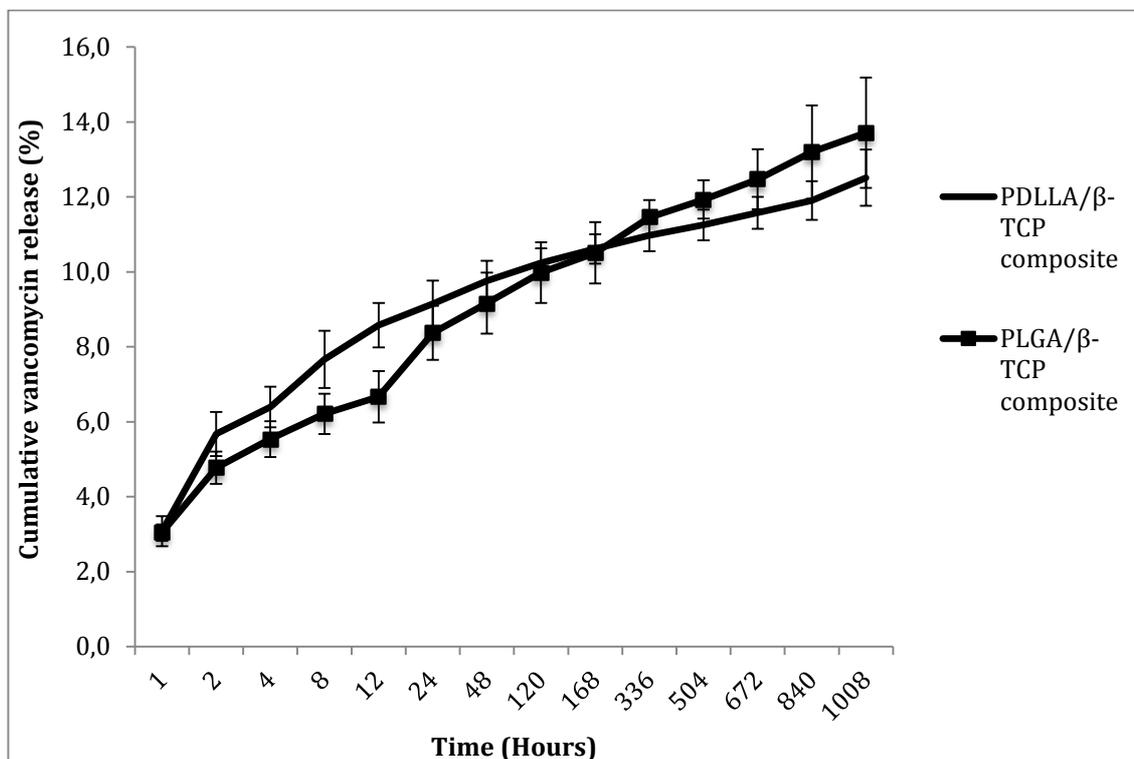

**Figure 17.** FTIR spectra of (a) PDLLA/ $\beta$ -TCP composite prior to SBF immersion, (b) PDLLA/ $\beta$ -TCP composite immersed in SBF for one week, (c) PDLLA/ $\beta$ -TCP composite immersed in SBF for three weeks, (d) PDLLA/ $\beta$ -TCP composite immersed in SBF for six weeks.

**Figure 18.** FTIR spectra of (a) PLGA/ $\beta$ -TCP composite prior to SBF immersion, (b) PLGA/ $\beta$ -TCP composite immersed in SBF for one week, (c) PLGA/ $\beta$ -TCP composite immersed in SBF for three weeks, (d) PLGA/ $\beta$ -TCP composite immersed in SBF for six weeks.

#### **4.4 Vancomycin Release Study for Vancomycin containing Polymer/Bioceramic Composites**

Both PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites released vancomycin for six weeks (Figure 19) and the calibration curve was given in Appendix A. PDLLA/ $\beta$ -TCP composites released  $2278 \pm 198 \mu\text{g}$  vancomycin while PLGA/ $\beta$ -TCP composites released  $2102 \pm 204 \mu\text{g}$  in one day. After six weeks, total amount of vancomycin released from composites were found  $3115 \pm 234 \mu\text{g}$  for PDLLA/ $\beta$ -TCP and  $3443 \pm 438 \mu\text{g}$  for PLGA/ $\beta$ -TCP.

**Figure 19.** Cumulative released vancomycin percentage of the composites.

The spectrophotometer analysis was validated by measuring three known vancomycin concentrations at three different time points (Table 1). The absorbances were almost same for each concentration with minimal standard deviation.

**Table 1.** The absorbance values of three different concentrations at three different times (Average±standard deviation).

	100 µg/ml	200 µg/ml	300 µg/ml
<b>Day 1</b>	0.045±0.003	0.090±0.002	0.133±0.002
<b>Day 2</b>	0.045±0.002	0.088±0.001	0.133±0.002
<b>Day 3</b>	0.044±0.001	0.089±0.002	0.133±0.002

#### 4.5 Content Uniformity of Vancomycin containing Polymer/Bioceramic Composites

The composites from each group (n=10) weighted and dissolved in dichloromethane. The dissolved solution was analyzed with spectrophotometer. The theoretical and measured vancomycin entrapment amounts were given in Table 2.

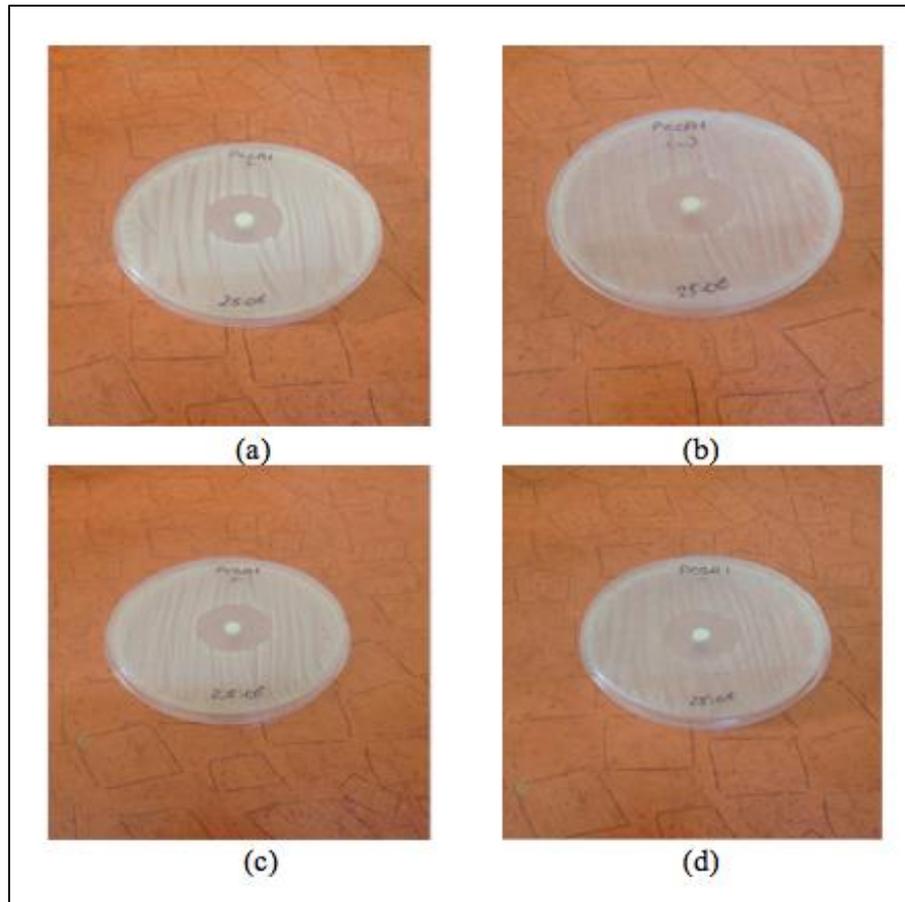

**Table 2.** Theoretical and actual vancomycin amounts in the composites.

Composite	Theoretical vancomycin amount	Measured vancomycin amount
PDLLA/ $\beta$ -TCP composite	23.077 $\pm$ 1.298 mg (21.346-25.876 mg)	20.680 $\pm$ 1.582 mg (18.636-23.179 mg)
PLGA/ $\beta$ -TCP composite	23.091 $\pm$ 0.948 mg (21.202-24.023 mg)	19.599 $\pm$ 0.931 mg (18.311-20.907 mg)

The results showed that actual vancomycin amounts were between 85% (17578.27  $\mu$ g for PDLLA/ $\beta$ -TCP composite and 16658,79  $\mu$ g for PLGA/ $\beta$ -TCP composite) and 115% (23782,36  $\mu$ g for PDLLA/ $\beta$ -TCP composite and 22538,37  $\mu$ g for PLGA/ $\beta$ -TCP composite) of the average content.

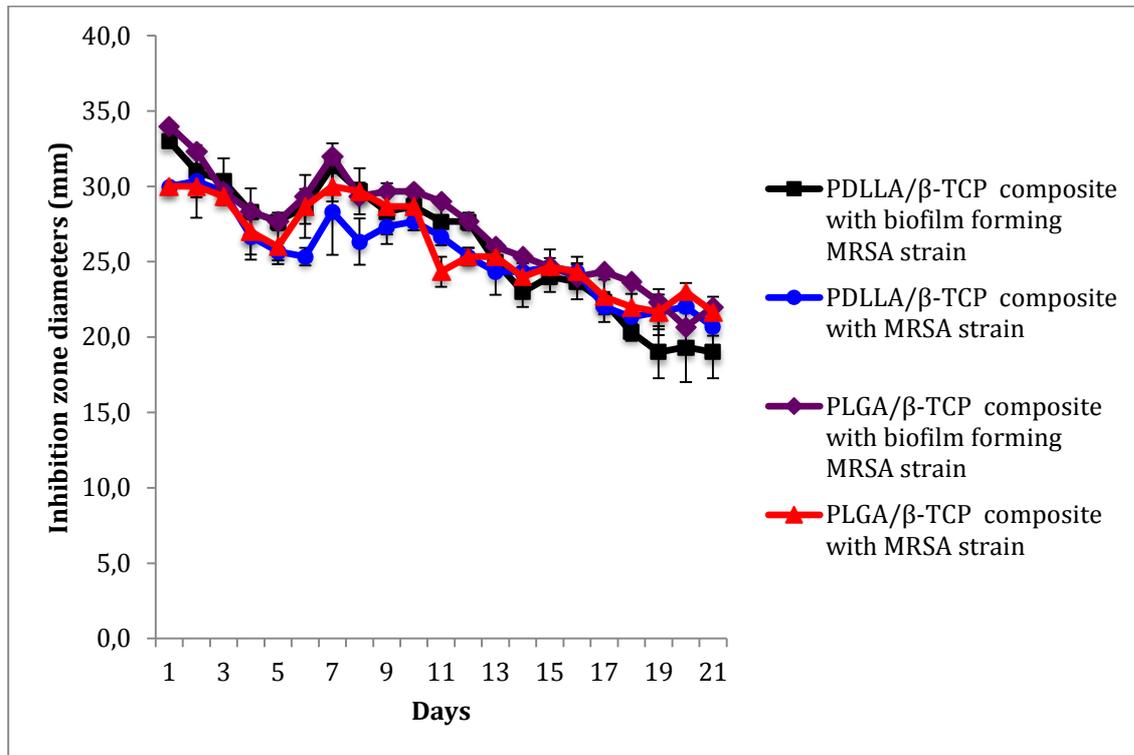

#### 4.6 Antibiotic Susceptibility Test for Vancomycin containing Polymer/Bioceramic Composites

The inhibition zone diameters of the composites were measured for 21 days and found that both vancomycin containing composites were susceptible to both strains of MRSA (for strain capable of forming biofilm and for strain which did not form any biofilm) for 21 days (Figure 20).

**Figure 20.** The inhibition zones of composites at day 21. (a) PDLLA/ $\beta$ -TCP composite with biofilm forming MRSA strain, (b) PDLLA/ $\beta$ -TCP composite with MRSA strain, (c) PLGA/ $\beta$ -TCP composite with biofilm forming MRSA strain and (d) PLGA/ $\beta$ -TCP composite with MRSA strain.

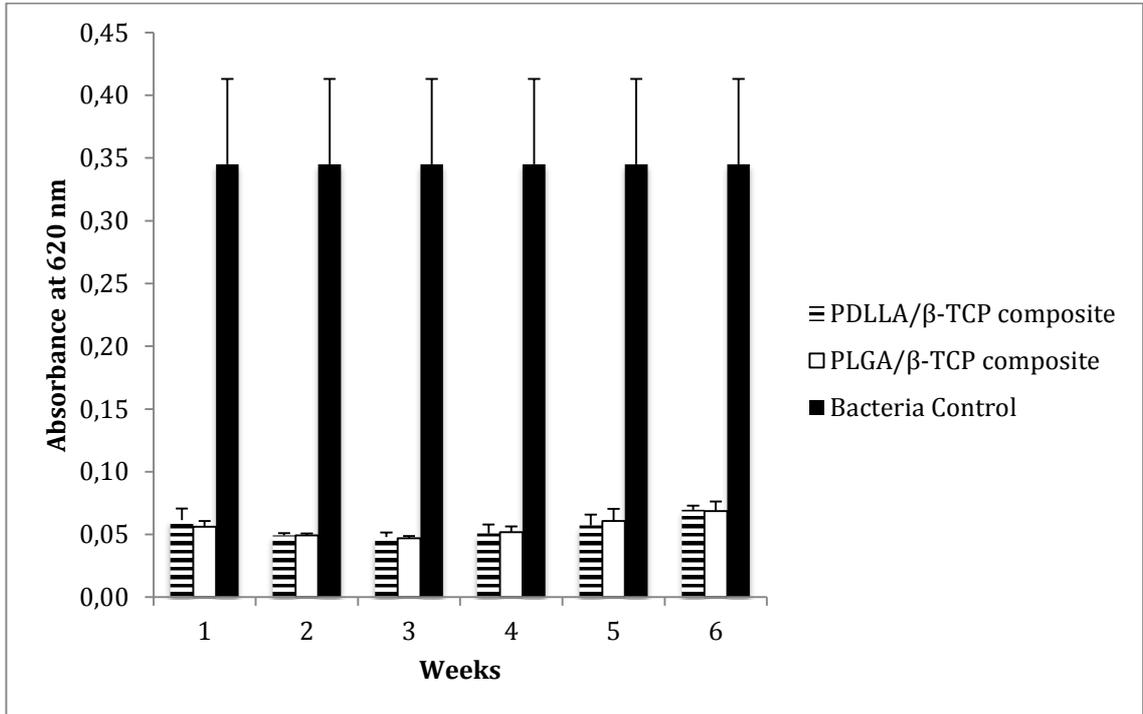

There was a statistically significant difference between groups ( $p:0.006$ ) (Figure 21). In PDLLA/ $\beta$ -TCP composites, there was a statistically significant difference between biofilm forming and non biofilm forming MRSA strains ( $p:0.039$ ). The  $p$  value indicating the statistically significant difference between PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites for biofilm forming MRSA strain was 0.021. According to Clinical and Laboratory Standards Institute (CLSI), the inhibition zone diameter must be equal or greater than 15 mm for the susceptibility of MRSA against vancomycin and the results showed that the inhibition zone diameters were never smaller than 18 mm during the study. Thus, MRSA was susceptible to the vancomycin containing composites during the study period.

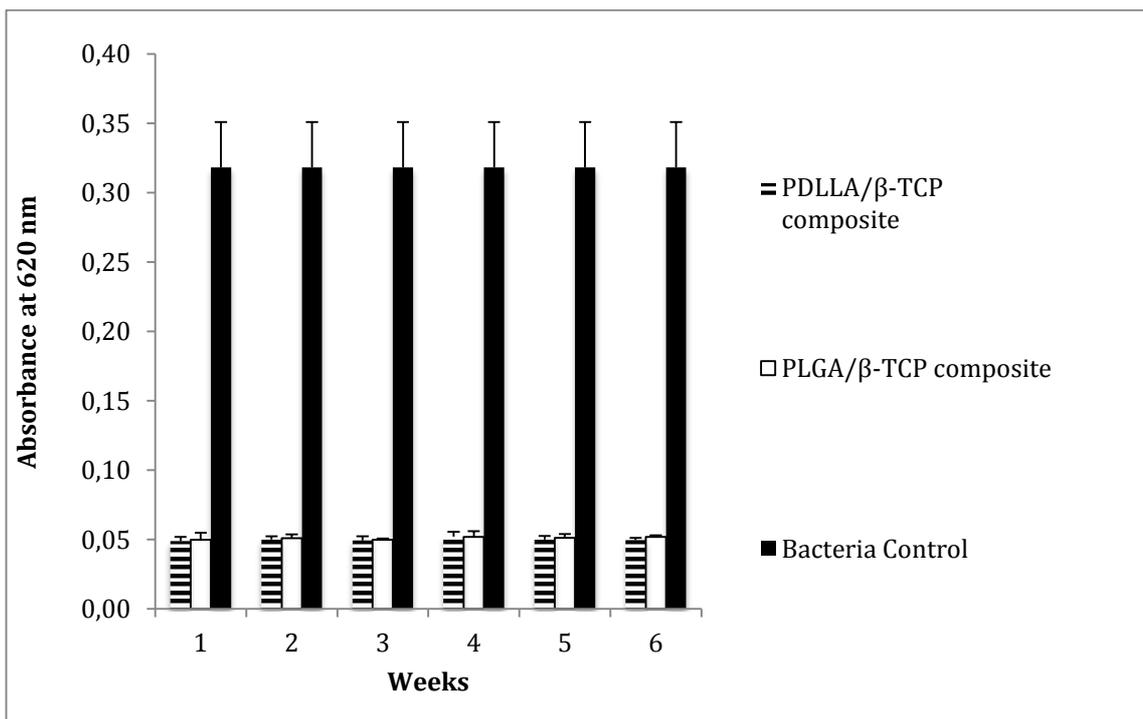

**Figure 21.** The inhibition zone diameters of the composites for 21 days.

#### **4.7 Biofilm Inhibition Study for Vancomycin containing Polymer/Bioceramic Composites**

There were slight differences in absorbance between the bacterial control and composites groups for biofilm inhibition study as seen in Figure 22, and 23. It was found that the released medium added to bacterial suspensions inhibited the formation of biofilm through six weeks. There was no statistically significant difference between the assays done with PBS or SBF, but in both assays, there was a statistically significant difference between composite groups and bacterial control ( $p < 0.05$ ).

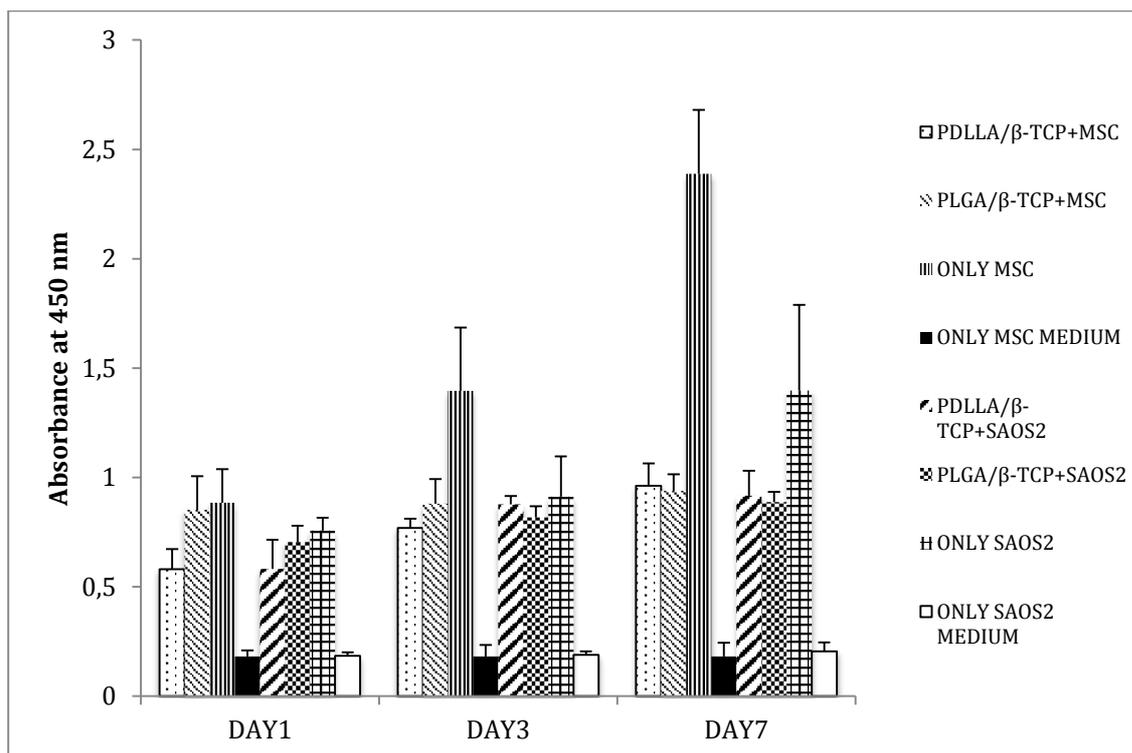

**Figure 22.** Absorbance of bacterial control, PDLLA/β-TCP and PLGA/β-TCP composites at 620 nm for SBF.

**Figure 23.** Absorbance of bacterial control, PDLLA/β-TCP and PLGA/β-TCP composites at 620 nm for PBS.

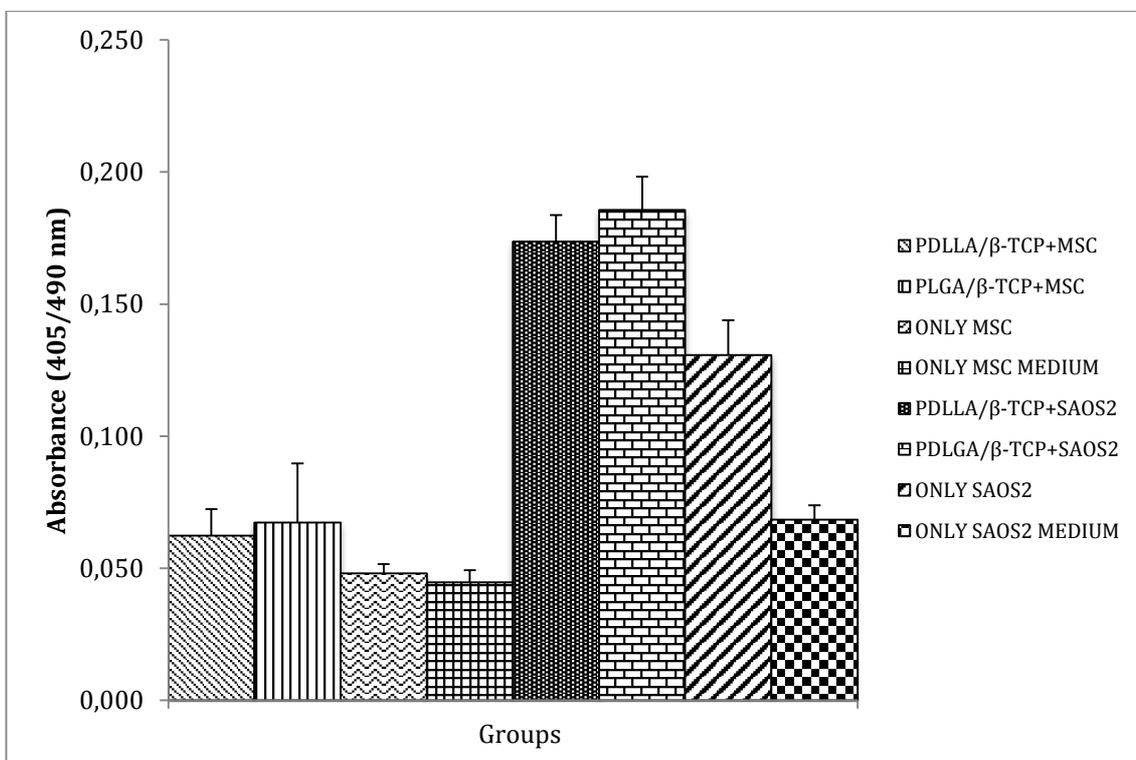

#### 4.8 Cell Culture Studies of Vancomycin containing Polymer/Bioceramic Composites

The proliferation of cells cultured on the surface of the composites was analyzed by WST-1. WST-1 based assays are colorimetric assays used for the quantification of cell proliferation, cell viability and cytotoxicity. The ascending absorbance in the assay indicated cell proliferation. The assay was done by using two different types of cells in order to figure out whether there was a difference in the proliferation of the cells. For both composite groups, the cells cultured on the composites proliferated from day 1 to day 7. However, the proliferation was not as high as the proliferation of cells cultured without any composite (Figure 24). Also mesenchymal stem cells proliferated more rapidly than SaOS-2 cells. The statistical difference in MSCs cultured without any composite was 0.001 and in SaOS-2 cells cultured without any composite was 0.048. For day 1, 3 and 7; there were differences in the PDLLA/ $\beta$ -TCP+MSC group (p:0.004), PDLLA/ $\beta$ -TCP+SaOS-2 group (p:0.014) and PLGA/ $\beta$ -TCP+MSC group (p:0.024).

**Figure 24.** Proliferation of the MSC and SaOS-2 cells in day 1, 3 and 7 according to the absorbance of WST-1 at 450 nm.

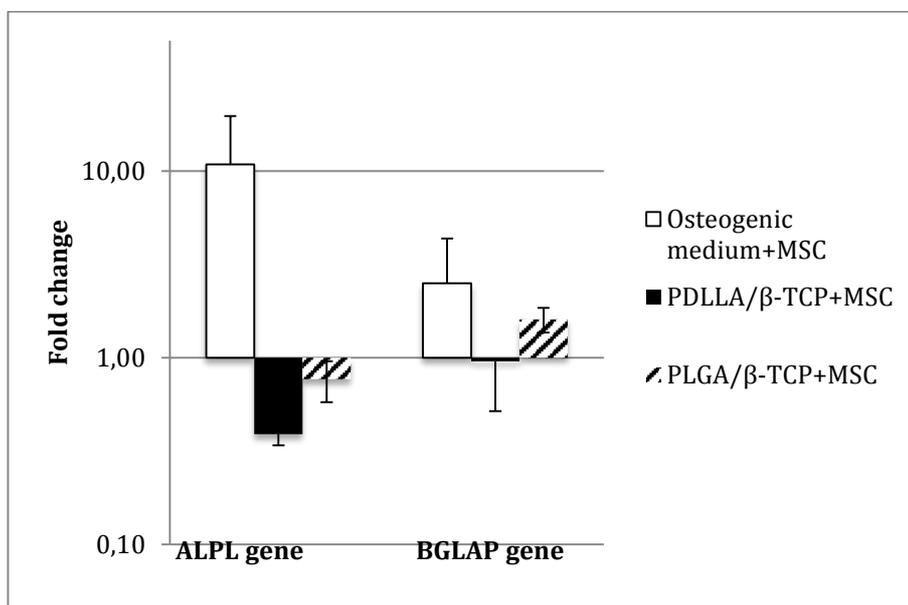

The alkaline phosphatase activities of cells cultured with the composites were quantified by using a ready to use buffered alkaline phosphatase substrate containing *p*-nitrophenylphosphate (pNPP). This colorless agent developed a yellow colored solution when reacted with the alkaline phosphatase and gave out an absorbance in order to quantify the activity. The ALP activities of the composites cultured with MSC were higher than the only MSC group but there was no statistical difference between these groups (Figure 25). The ALP activities of the composites cultured with SaOS-2 cells were also higher than the only SaOS-2 cell group, but this time there was a statistical difference between the groups (p:0.003) (PDLLA/ $\beta$ -TCP composite+SaOS-2 cells versus only SaOS-2 cells; p: 0.011, PLGA/ $\beta$ -TCP composite+SaOS-2 cells versus only SaOS-2 cells; p: 0.006).

**Figure 25.** ALP activity of the groups at day 21 according to their absorbances at 405 nm.

#### 4.9 Real Time Quantitative Polymerase Chain Reaction (RT-qPCR) Assay for Vancomycin containing Polymer/Bioceramic Composites

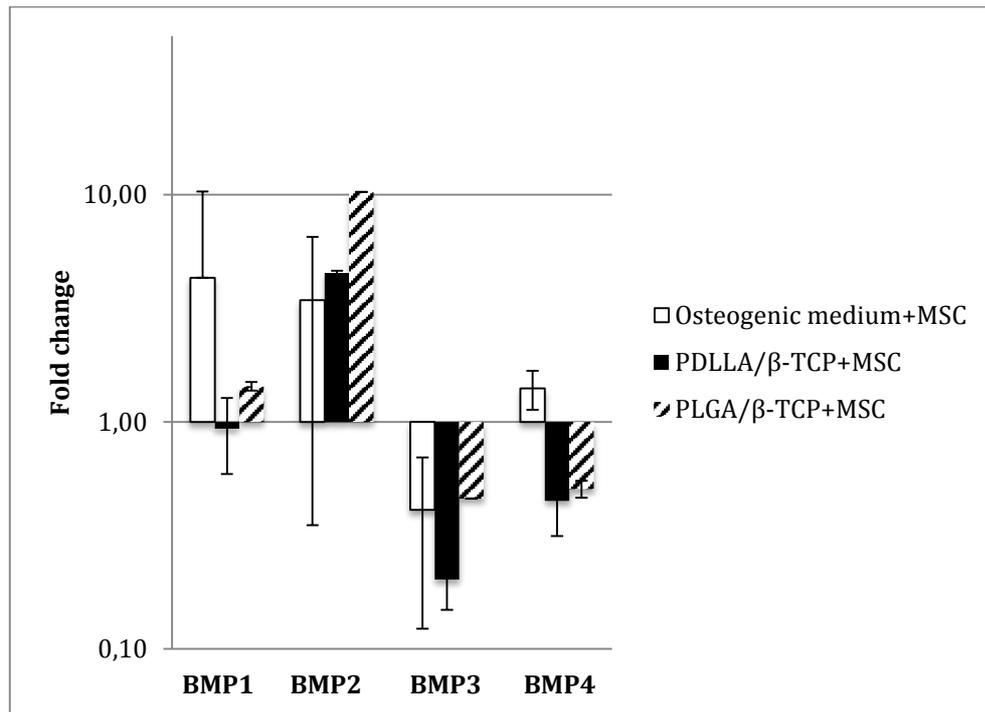

In the RT-qPCR assay, there was no AHSG, BMP5, COL2A1, DMP1, FGF3, MMP9 gene expressions in any groups. Alkaline phosphatase gene, ALPL expressed 10.87±8.85 fold higher in osteogenic medium group while the expression was decreased for PDLLA/β-TCP+MSC (0.39±0.05) and PLGA/β-TCP+MSC (0.77±0.19).

**Figure 26.** Fold change of ALPL and BGLAP gene expressions between groups.

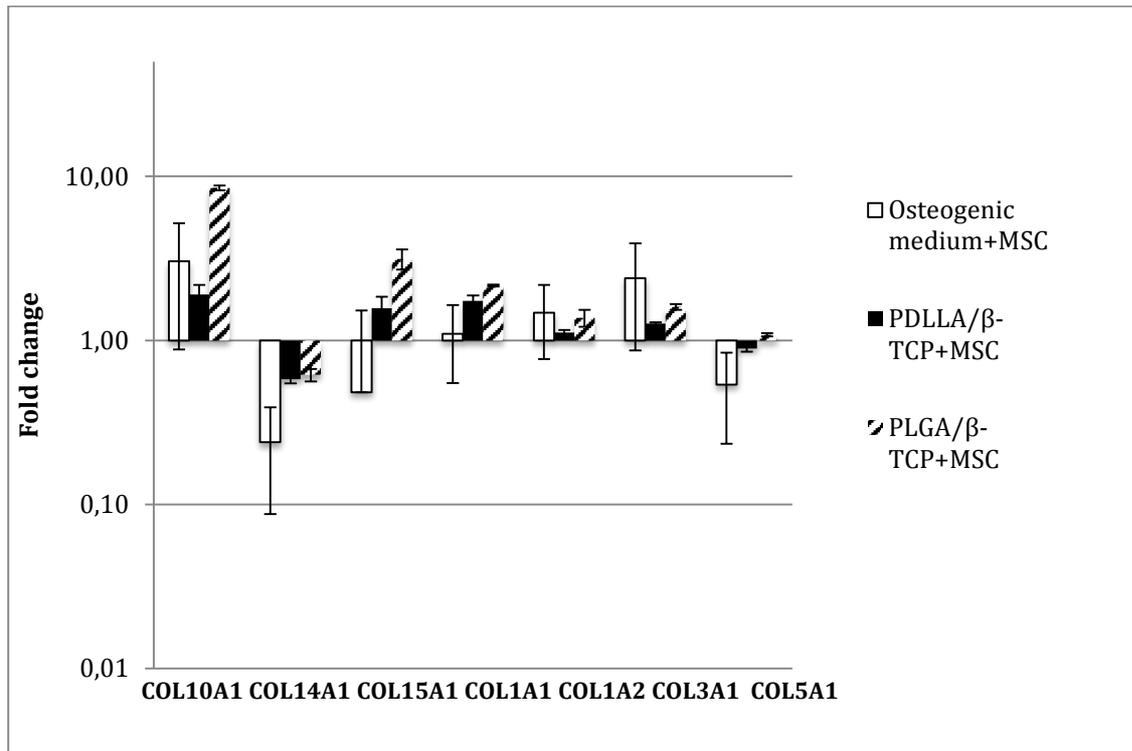

Bone gamma carboxyglutamic acid containing protein (Bglap) is encoded by BGLAP gene and used as a biochemical marker for bone formation. BGLAP gene expression was 2.52±1.85, 0.96±0.44 and 1.71±0.24 fold higher in osteogenic medium group, PDLLA/β-TCP group and PLGA/β-TCP group, respectively (Figure 26). In the bone morphogenic protein family, the distinct fold changes were observed for BMP-1, BMP-2, BMP-3 and BMP-4 (Figure 27). In osteogenic medium group, BMP-1 gene expression was 4.31±6.02 fold higher while BMP-2 gene expression was 3.43±3.08, BMP-3 gene expression was 0.41±0.29 and BMP-4 gene expression was 1.40±0.27 fold higher. In PDLLA/β-TCP group, BMP-1 gene expression was like control (0.93±0.34) but BMP-2 gene expression was 4.52±0.11 fold higher.

BMP-3 and BMP-4 gene expressions were  $0.20 \pm 0.05$  and  $0.45 \pm 0.13$ . In PLGA/ $\beta$ -TCP group, fold change for BMP-1, BMP-2, BMP-3 and BMP-4 genes were  $1.43 \pm 0.06$ ,  $10.28 \pm 0.02$ ,  $0.46$  and  $0.51 \pm 0.04$ , respectively.

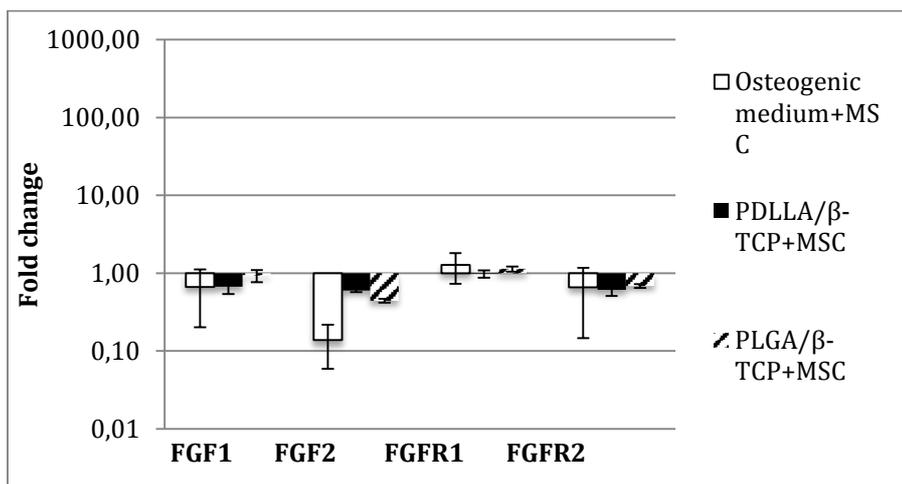

**Figure 27.** Fold changes of BMP-1, BMP-2, BMP-3 and BMP-4 gene expressions between groups.

For the collagen genes group, the distinct fold changes were observed for COL10A1, and COL3A1 (Figure 28). There was no gene expression for COL2A1 gene in any group.

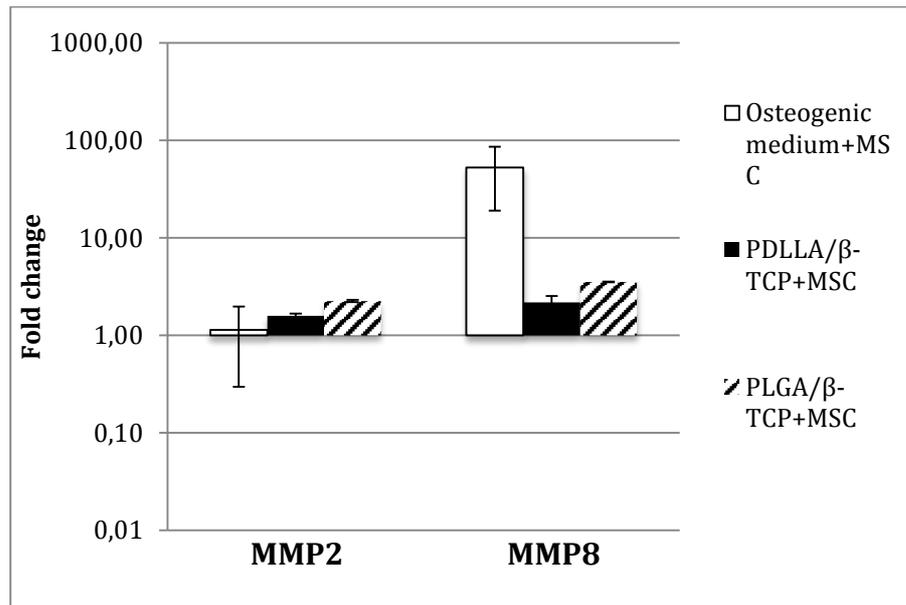

**Figure 28.** Fold changes of collagen gene expressions between groups.

For fibroblast growth factor (FGF) genes, the expressions were all decreased except FGFR1 gene in all groups (Figure 29).

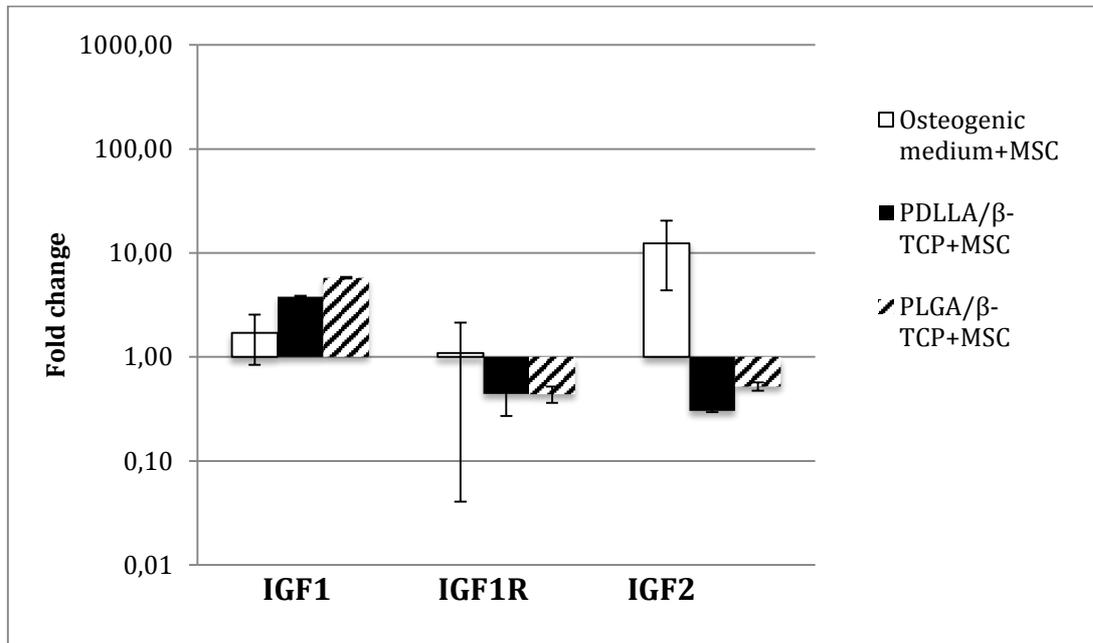

**Figure 29.** Fold changes of FGF1, FGF2, FGFR1 and FGFR2 gene expressions between groups.

For matrix metalloproteinases (MMP), there was no expression for MMP9 and MMP10 in any group. On the contrary, MMP2 and MMP8 gene expression were increased in all groups according to control (Figure 30).

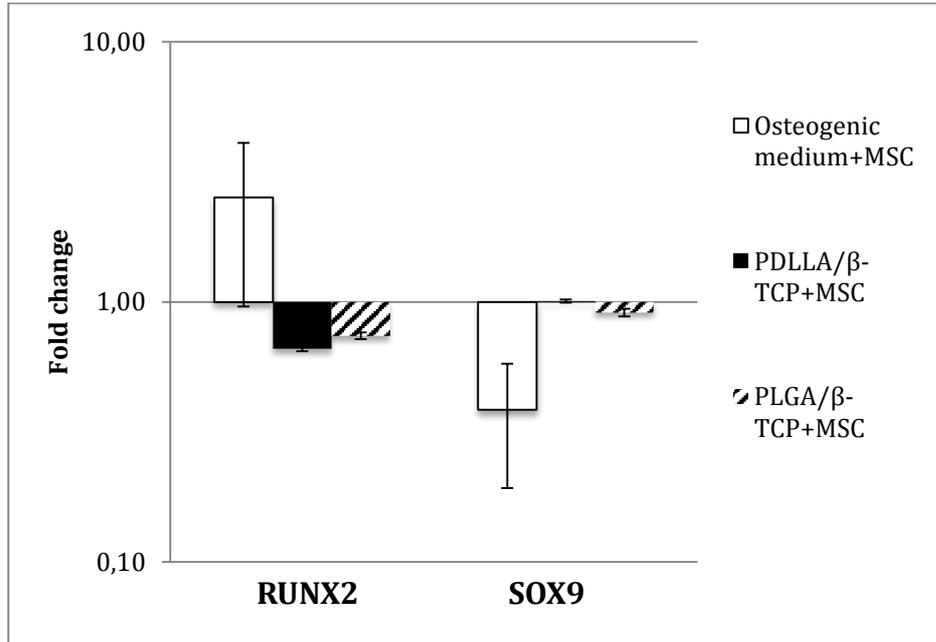

**Figure 30.** Fold changes of MMP2 and MMP8 gene expressions between groups.

Insulin like growth factors 1 and 2 (IGF1 and IGF2) showed different results in the manner of gene expression. For IGF1, in all groups the gene expression was increased while for IGF2, the gene expression was decreased in composite groups while it was increased for osteogenic medium group (Figure 31).

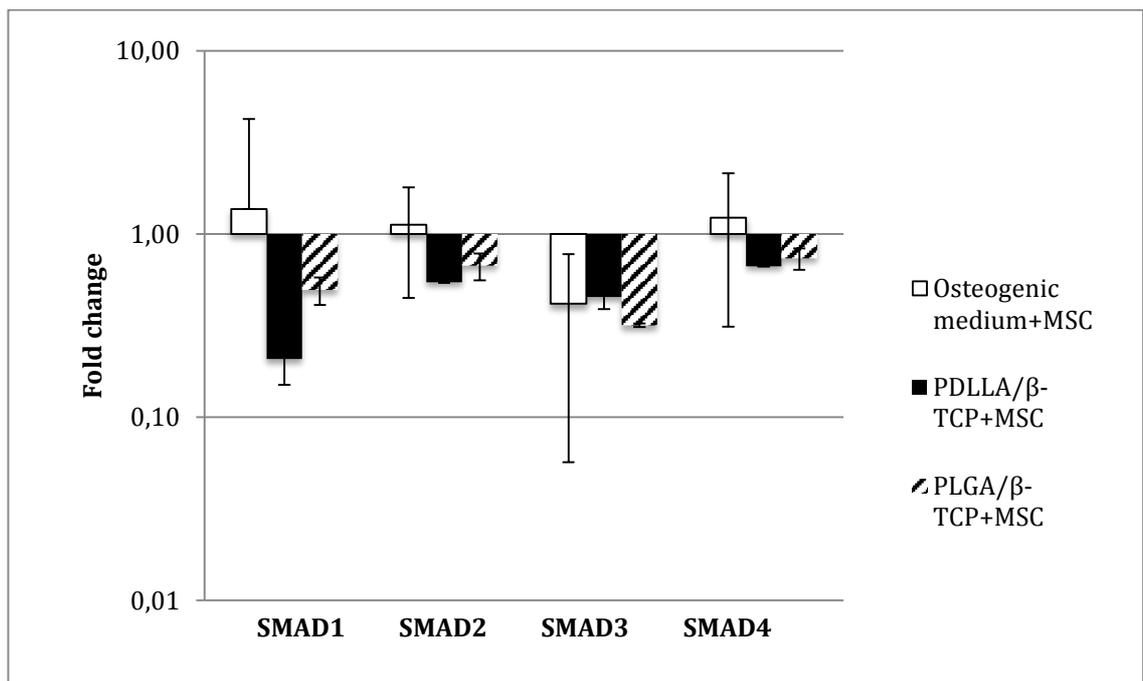

**Figure 31.** Fold changes of IGF1, IGF1R and IGF2 gene expressions between groups.

The transcription factors related with osteoblast differentiation and skeletal development, runt related transcription factor 2 (RUNX2) and sex determining region Y box 9 (SOX9) were both decreased in composites groups. For osteogenic medium group, RUNX2 expression was increased while it was decreased for SOX9 (Figure 32).

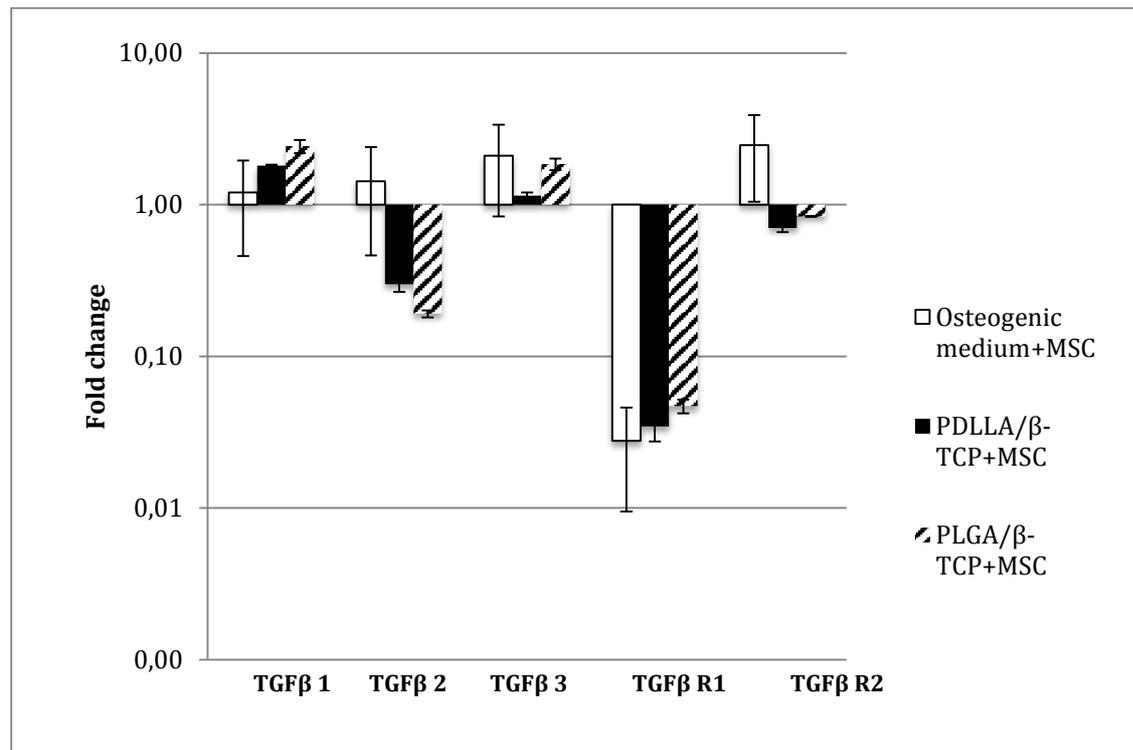

**Figure 32.** Fold changes of RUNX2 and SOX9 gene expressions between groups.

The SMAD gene expressions were decreased for both composite groups. For osteogenic medium group, all SMAD gene expressions except SMAD 3 were increased (Figure 33).

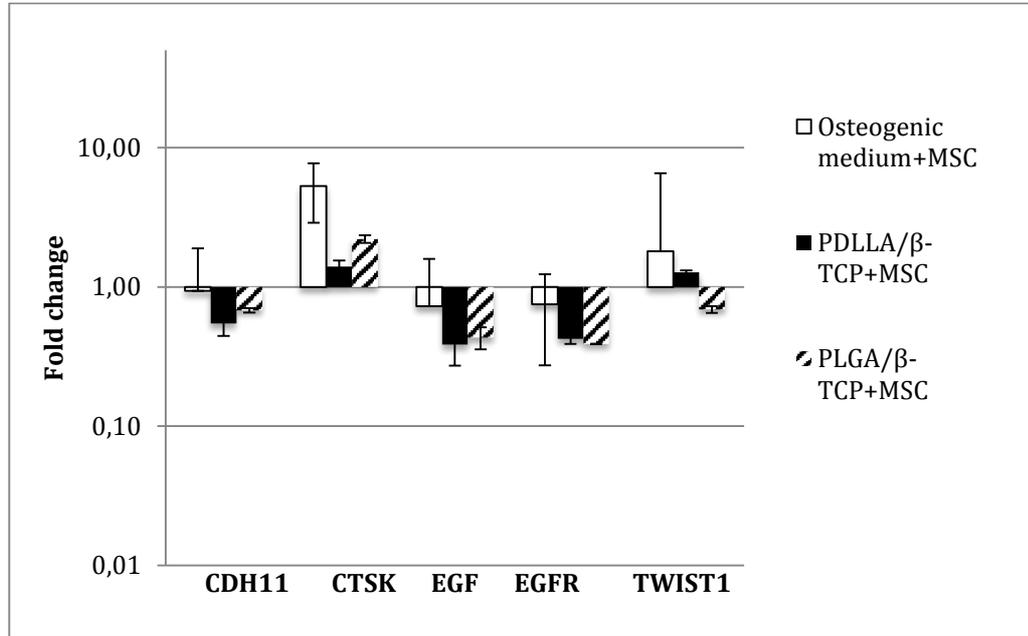

**Figure 33.** Fold changes of SMAD 1, 2, 3 and 4 gene expressions between groups.

The gene expressions related with transforming growth factor (TGF) and its receptor were given in Figure 34. The expression of genes expressing TGF $\beta$ 1 and TGF $\beta$ 3 were increased in all groups; but for the receptor 2 of transforming growth factor beta, the genes expressions were decreased for both composite groups (Figure 34).

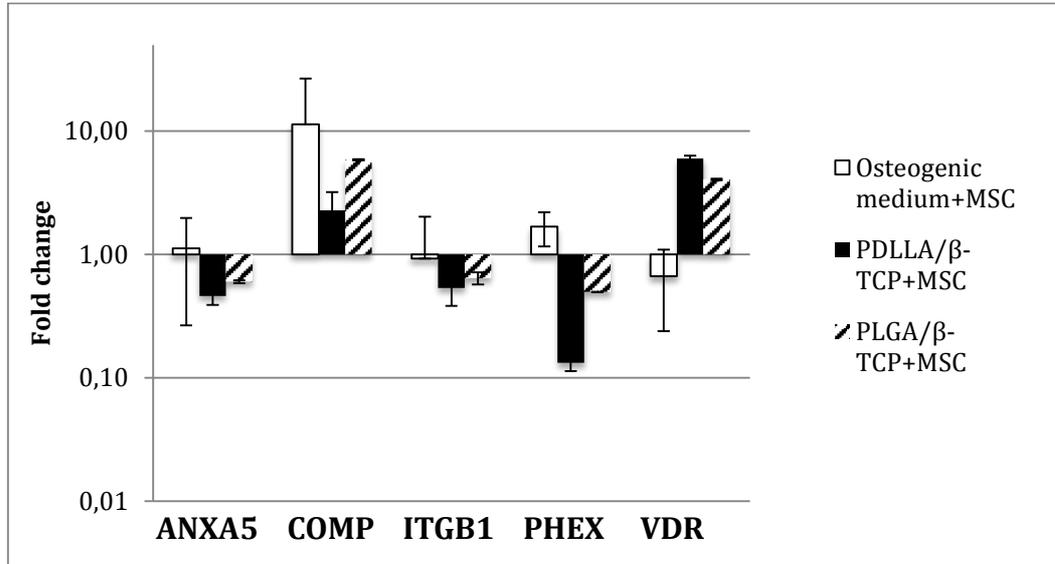

**Figure 34.** F Fold changes of TGF $\beta$ 1, TGF $\beta$ 2, TGF $\beta$ 3, TGF $\beta$ R1 and TGF $\beta$ R2 gene expressions between groups.

The expressions of CDH11, CTSK, EGF, EGFR and TWIST1 were given in Figure 35. The expression of CTSK was increased in every group while the expressions of CDH11, EGF and EGFR were all decreased.

**Figure 35.** Fold changes of CDH11, CTSK, EGF, EGFR, and TWIST1 gene expressions between groups.

The expressions of ANXA5, ITGB1 and PHEX were all downregulated in composites group according to control (Figure 36). In the expression of twist homolog 1 (TWIST1) gene, osteogenic medium and PDLLA/β-TCP composite group showed elevation in fold change while, PLGA/β-TCP composite group showed a decrease. The expression of phosphate regulating endopeptidase (PHEX) gene was decreased for both composites unlike osteogenic medium group.

**Figure 36.** Fold changes of ANXA5, COMP, ITGB1, PHEX and VDR gene expressions between groups.

For determining the genes fold changes significance between the groups, the binary logarithm of the  $\Delta\Delta Ct$  values were calculated and  $\pm 2$  fold changes were taken as significant. The significant values were given in grey boxes in Table 3.

**Table 3.** The upregulation or downregulation of genes in the test groups according to control.

Fold Up- or Down-regulation according to Control			
Gene	Osteogenic Medium + MSC	PDLLA/β-TCP + MSC	PLGA/β-TCP + MSC

## CHAPTER 5

### DISCUSSION

Osteomyelitis is a bone infection, generally caused by *Staphylococcus aureus* (100). When the infection staged to chronic level, the infection can not be treated with antibiotics alone. Poor blood circulation in the infection area due to the compression of vascular channels and bone necrosis makes osteomyelitis a persistent disease (101). In order to treat osteomyelitis, local drug delivery systems are generated. These systems released the entrapped drug in a controlled manner while being biocompatible.

In this study, vancomycin containing PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites were fabricated. The composites had smooth surfaces with microcracks. EDS spectras confirmed the content of the composites by giving carbon peaks resembling polymer, phosphorous and calcium peaks resembling bioceramic and chloride resembling the antibiotic, vancomycin HCl. The composites and their materials were analyzed with FTIR and found that composites had similar adsorption bands with their contents.

In the degradation study, PDLLA/ $\beta$ -TCP composites lost  $67.98 \pm 1.5\%$  of their weight by week six while PLGA/ $\beta$ -TCP composites only lost  $19.13 \pm 0.2\%$  of their weight. This weight loss was likely due to ionic release of TCP and perhaps to a smaller extent, hydrolytic degradation of polymer. The addition of TCP is hypothesized to accelerate the degradation of the polymer. Since the TCP particles were only physically blended into the polymer, they occupied random spaces in the polymer. After the composite was immersed in solution, the hydrophilic TCP particles tended to fall off and interact with the surrounding medium. The TCP was converted to its more stable soluble phase that is apatite. The falling of TCP also created voids within the polymer, thus exposing their surfaces to hydrolytic attack and weakening the

overall structure of the polymer (102). The molecular weight of PDLLA was between 10-18 kDa, whereas the molecular weight of PLGA was 190-240 kDa. Since the molecular weight of PDLLA was lower than the molecular weight of PLGA, PDLLA/ $\beta$ -TCP composite degraded more rapidly. Also during the fabrication of the composites, there was a pounding step after dissolving all the components in dichloromethane. In this step, PDLLA/ $\beta$ -TCP composites had larger structures than PLGA/ $\beta$ -TCP composite, so during the packing of the composites this may lead the weakness of the composite. The water uptake percent of the composites were decreased by week 6 in both composite types. Baro et. al. characterized the gentamicin bone implants made up of PDLLA, TCP and hydroxyapatite in vitro. According to study, the mass loss and water uptake of the implants were increased by 8 weeks (103). But in this study, same implants were used all through the time. In our study, we used fresh samples for every time point. As a result, our water uptake results were not same with the literature. On the other hand, higher content of hydrophilic TCP in the composites facilitated the absorption and diffusion of SBF and resulted in higher water absorption. This increased water absorption resulted in the higher weight loss (104). The water absorption process is a balance between the dissolution of oligomers in the solution and water uptake of the residual material. Accumulation of the hydrophilic degradation products inside the composites resulted in the increase of water absorption during the whole degradation process. When water absorption reached a certain value, the increase rate began to reduce as a result of the dissolution of the degradation products (83).

The bone like apatite formation on the surface of composites were proved with SEM, EDS and FTIR results. TCP in the composites in this study dissolved in SBF solution, suggesting  $\text{OH}^-$ , calcium and phosphate ions combined to form an apatite (105). SEM results showed the agglomeration of the apatite particles on the surface of the composites and EDS results gave the Ca/P molar ratio of the apatite. It was found that all the apatite formed on the surface of the composites were non-stoichiometric apatite with Ca/P molar ratio  $\neq$  1.67 (105). But, the Ca/P atomic ratios were 1.57, 1.69 and 1.88, respectively, for the PDLLA/  $\beta$ -TCP composite immersed for 1, 3 and 6 weeks and 1.66, 1.73 and 1.77 respectively, for the PLGA/  $\beta$ -TCP

composite immersed for 1, 3 and 6 weeks, which were comparable to the value (1.67) for stoichiometric HA (52). The apatite deposition on the surface of the composite reflected the in vitro bioactivity of the composites (106).

Both PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites released vancomycin for six weeks. PDLLA/ $\beta$ -TCP composite released only 11.21% of its vancomycin while PLGA/ $\beta$ -TCP released 11.64%. These results were quite low when compared with the literature (100). In literature most of the drug delivery system released 80-100% of their drug content during the study. We mentioned before that, our composites did not have a porous structure and the drug can only be released from the microcracks. Therefore, the composites can continue to release their drug content for long times. Also, the composites showed a burst effect in 24 hours. We assumed that this initial burst was related with the diffusion of vancomycin located near to the surface of the composites (107).

Both biofilm forming MRSA strain and MRSA strain without any biofilm formation capability were susceptible to the vancomycin released from both composites. The inhibition zone diameters were measured for 21 days and the diameters changed day by day according to the released vancomycin. The diameters were decreased by day 21 but the bacteria were still susceptible for the composites according to CLSI guidelines (108).

Some strains of MRSA are capable of biofilm forming and this biofilm protects the bacteria from the environmental conditions. Here we conducted a biofilm inhibition study with both composites. We diluted the bacterial solutions by adding 20  $\mu$ l of the vancomycin release mediums from different times and incubated the plates for 2 days (100). We found that both composites inhibited the biofilm formation for six weeks. This confirms the antibacterial properties of vancomycin containing composites. Biofilm inhibition study was conducted to mimic a condition whereby biofilm formation has been established in osteomyelitis. Both vancomycin containing PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites can eliminate the formation of the biofilm. The result shows these particles are able to release drugs at a concentration sufficient to completely inhibit the formation of a biofilm. Inhibition of biofilm formation in osteomyelitis is beneficial because this is the key to treat the infection

(100).

The biocompatibility of the composites were analyzed by the proliferation assay done with WST-1. WST-1 based assays are colorimetric assays used for the quantification of cell proliferation, cell viability and cytotoxicity based on the cleavage of a tetrazolium salt (WST-1) by mitochondrial dehydrogenases in viable cells. Increased enzyme activity leads to an increase in the amount of formazan dye, which is measured with a spectrophotometer (109). According to results, the cells on the composites proliferated by day 7 for both MSC and SaOS-2 cells. There was no any significant difference between PDLGA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites at any time point. But, the proliferation of only cell in cell culture plate was higher than the composite group. Since the surface area of the cell culture plate was larger, cells proliferated more in the wells than the surfaces of the composites.

Alkaline phosphatase (ALP) is an early marker expressed by preosteoblasts and mineralizing osteoblasts (105). We searched the alkaline phosphatase activity of the composites with MSC and SaOS-2 cells for 21 days and found that the composite groups had more ALP activity than only cell groups but there was no significant difference between the groups for MSC. The significant differences in the SaOS-2 cell groups were related with osteoblast-like nature of the SaOS-2 cells. Since these cells had osteoblast-like properties, it was expected that these cells showed higher ALP activity than MSC (110).

On the other hand, according to RT-PCR results, alkaline phosphatase gene expression (ALPL) was decreased for both composite groups. This conflict may be related to the RT-PCR studies were conducted in non-contact mode while the ALP activity study was done in contact mode. Also, ALP activity study was lasted for 21 while RT-PCR studies were lasted for 14 days. The expression of ALPL was low for both composites but the differences in the fold changes were not significant. The cells cultured with osteogenic medium showed higher ALPL expression related with the synergetic effect of the dexamethasone. The gene expression levels of osteocalcin (bone gamma-carboxyglutamic acid-containing protein (BGLAP)) a late secreted protein produced by mature osteoblasts, was also higher in osteogenic

medium group according to composites groups. BMP1 or procollagen C proteinase, a secreted metalloprotease requiring calcium and needed for cartilage and bone formation (111) was upregulated significantly in osteogenic medium group, whereas it was downregulated in both composites groups. RUNX2 is a key regulator of chondroblast and osteoblast differentiation, and of bone development *in vivo* (112). RUNX2 regulates the expression of major extracellular matrix genes (including alkaline phosphatase, osteopontin, osteocalcin, type I collagen, and type X collagen) expressed by chondroblasts and osteoblasts. Expression and activation of RUNX2 is regulated by many bone derived growth factors, including bone morphogenetic proteins (BMPs). BMPs form a unique group of proteins within the TGF- $\beta$  super family of genes, and play pivotal roles in the regulation of cartilage and bone development. BMP-activated Smads (Smad1, -5, and -8) induce RUNX2 gene expression, and Smads interact physically with the Runx2 protein to induce osteoblast differentiation (113). Here in our study, BMP1 was only upregulated in osteogenic medium group. But for BMP2, there was significant upregulation for both PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites and the upregulation was higher than osteogenic medium group. On the contrary, BMP4 expression was downregulated both composites group. Nevertheless, this upregulation was not induced the upregulation of the SMADs 1, 2, 3 and 4 in composites groups and as a result there was no RUNX2 upregulation. By the way, neither the upregulation of RUNX2 in the osteogenic medium group, nor the downregulation in the composites groups had any significant difference. TGF- $\beta$ 1, another factor involved in osteoblast proliferation and differentiation was also upregulated in composites groups but this increase did not lead the upregulation of the SMAD genes. TGF- $\beta$ 2, one of TGF- $\beta$  isoforms within bone matrix, modulates the differentiation of osteoblasts and the proliferation of osteoprogenitor cells (114). Here, only the cells cultured with osteogenic differentiation medium showed the upregulation of TGF- $\beta$ 2, so that the cells in composite groups could not differentiate into osteoblasts. Differentiation of human mesenchymal stem cells into bone forming cells is stimulated by endothelial growth factor, EGF (115). Again, the expression of both EGF and its receptor EGFR were downregulated for both composites groups.

## CHAPTER 6

### CONCLUSION

As a conclusion, PDLLA/ $\beta$ -TCP and PLGA/ $\beta$ -TCP composites were developed and characterized. Vancomycin containing PDLLA/ $\beta$ -TCP and vancomycin containing PLGA/ $\beta$ -TCP composites released  $3.1 \pm 0.2$  mg and  $3.4 \pm 0.4$  mg vancomycin for six weeks, respectively and had antibacterial activity against MRSA while also having biofilm inhibition ability. Vancomycin containing PDLLA/ $\beta$ -TCP and vancomycin containing PLGA/ $\beta$ -TCP composites were biocompatible with Mesenchymal Stem Cells and SaOS-2 osteosarcoma cells and the apatite formation on the surface of the composites indicating the bioactivity of the material. In contact mode, the composites showed ALP activity at 21 days with both MSC and SaOS-2 cells.

Beside the biocompatibility and antibacterial properties of the composites, the composites did not show any osteogenic differentiation, and bioconduction activity in non contact mode according to RT-PCR studies. The vancomycin containing PDLLA/ $\beta$ -TCP and vancomycin containing PLGA/ $\beta$ -TCP composites were not induced the differentiation of mesenchymal stem cells by not expressing some of the osteogenesis related signalling molecules. This may due to the absence of an osteogenic medium, since mesenchymak stem cells cannot differentiate into osteoblast just with the help of the composite. Also, the non contact mode study design may effect the gene expression results, since in the contact mode the gene expression can be elevated.

To conclude, future studies can be conducted both *in vitro* and *in vivo* in order to find out the osteogenic capability of the composites in contact mode.

## APPENDIX A

### CALIBRATION CURVE FOR VANCOMYCIN

**Figure 37.** Calibration curve of vancomycin

## APPENDIX B

### GENE LIST FOR RT-PCR CUSTOM PLATES

**Table 4.** Gene List for RT-PCR custom plates

Gene Name	Gene Description	Forward Primer Sequence	Reverse Primer Sequence
AHSG	alpha-2-HS-glycoprotein	TGCTAAAGAGGC CACAGAGG	TGTTGCCTTACA AAAGCCATATT
ALPL	alkaline phosphatase, liver/bone/kidney	AGAACCCCAAAG GCTTCTTC	CTTGGCTTTTCCT TCATGGT
ANXA5	annexin A5	TCTTCGGAAGGC TATGAAAGG	GGGATGTCAACA GAGTCAGGA
BGLAP	bone gamma-carboxyglutamate (gla) protein	CCAGCCCTATGG ATGTGG	TTTTTCAGATTTCCT CTTCTGGAGTT
BMP1	bone morphogenetic protein 1	TATGTGGAGGTC CGAGATGG	GAGTTTGGACCC GCAGAA
BMP2	bone morphogenetic protein 2	GACTGCGGTCTC CTAAAGGTC	GGAAGCAGCAAC GCTAGAAG
BMP3	bone morphogenetic protein 3	CCCAAGTCCTTT GATGCCTA	TCTGGATGGTAG CATGATTGA
BMP4	bone morphogenetic protein 4	GAGGAAGGAAG ATGCGAGAA	GCACTACGGAAT GGCTCCT
BMP5	bone morphogenetic protein 5	GCAATAAATCCA GCTCTCATCA	TGTTTTTGCTCAC TTGTGTTATAAT CT
BMP6	bone morphogenetic protein 6	ACATGGTCATGA GCTTTGTGA	ACTCTTTGTGGT GTCGCTGA
CALCR	calcitonin receptor	CGCTTGCGGTGG TATTATCT	GGTAATAGCATG GATAGTGGTTGG
CDH11	cadherin 11, type 2,	CATCGTCATTCT CCTGGTCA	TCAAAGACAATG AGTGGTTCTTTC

**Table 4.** (continued)

COL10 A1	collagen, type X, alpha 1	CAGTTCTTCATTC CCTACACCA	AGGACTTCCGTA GCCTGGTT
COL14 A1	collagen, type XIV, alpha 1	GACCCCTCATCA TGTTCTGC	ATGGCTTCCAGC TCATCTTG
COL15 A1	collagen, type XV, alpha 1	TGATGGTCGAGA CATAATGACA	GGAGCCATGCCA AATGAC
COL1 A1	collagen, type I, alpha 1	AGGTGAAGCAGG CAAACCT	CTCGCCAGGGAA ACCTCT
COL1 A2	collagen, type I, alpha 2	TCTGGAGAGGCT GGTACTGC	GAGCACCAAGAA GACCCTGA
COL2 A1	collagen, type II, alpha 1	TTTCAAGGCAAT CCTGGTG	TCCAGGTTTCC AGCTTCAC
COL3 A1	collagen, type III, alpha 1	ACTGGAGCACGG GGTCTT	TCCTGGTTTCCC ACTTTCAC
COL5 A1	collagen, type V, alpha 1	TCTTGGCCCAA GAAAACC	GGCGTCCACATA GGAGAGC
COMP	cartilage oligomeric matrix protein	GGGTCCCAATG AAAAGG	CCTTTTGGTCGTC GTTCTTC
CTSK	cathepsin K	CGAAGCCAGACA ACAGATTTC	AGAGCAAAGCTC ACCACAGG
DMP1	dentin matrix acidic phosphoprotein 1	TTCCTTTGGGGA TTATCCTGT	TGCCTGAGCCAA ATGACC
EGF	epidermal growth factor	CCTCAGATGGGA AAACGTG	GTTCTTTAGATC AACTTCACCACC T
EGFR	epidermal growth factor receptor	CAGCCACCCATA TGTACCATC	AACTTTGGGCGA CTATCTGC
FGF1	fibroblast growth factor 1 (acidic)	AATCAGCCAAAG AGCCTGTC	CAAAACAGAGCA GGGA ACTACC
FGF2	fibroblast growth factor 2 (basic)	CCCGACGGCCGA GTTGAC	CACATTTAGAAG CCAGTAATCT
FGF3	fibroblast growth factor 3	GCGTCTGGGTTC TCAGCTAT	CTTGGGCCCTCT TCAGTTC
FGFR1	fibroblast growth factor receptor 1	AAGATTGGCCCA GACAACC	GCACCTCCATCT CTTTGTGC
FGFR2	fibroblast growth factor receptor 2	GACCCAAAATGG GAGTTTCC	GACCACTTGCCC AAAGCA

**Table 4.** (continued)

IGF1	insulin-like growth factor 1	TGCTTTTGTGATT TCTTGAAGG	GCAGAGCTGGTG AAGGTGA
IGF1R	insulin-like growth factor 1 receptor	TCAGCGCTGCTG ATGTGT	GGCTCATGGTGA TCTTCTCC
IGF2	insulin-like growth factor 2	GCTGGCAGAGGA GTGTCC	GGGATTCCCATT GGTGTCT
ITGB1	integrin, beta 1 (fibronectin receptor, antigen CD29 includes MDF2, MSK12)	CTTGGAACAGAT CTGATGAATGA	TCCACAAATGAG CCAAATCC
MMP10	matrix metalloproteinase 10	CAAAGAGGAG GACTCCAACA	TTCACATCCTTT CGAGGTTG
MMP2	matrix metalloproteinase 2	TATTTGATGGCA TCGCTCAG	ACAGTCCGCCAA ATGAACC
MMP8	matrix metalloproteinase 8	GGGAACGCACTA ACTTGACC	TTCAAAGGCATC CTTGATAGC
MMP9	matrix metalloproteinase 9	ATCCGGCACCTC TATGGTC	CAGACCGTCGGG GGAG
PHEX	phosphate regulating endopeptidase homolog, X-linked	AGTGCATCCACC AACCAGAT	TTCCCCAAAAGA AAGGCTTC
RUNX2	runt-related transcription factor 2	GCCTAGGCGCAT TTCAGAT	CTGAGAGTGGAA GGCCAGAG
SMAD1	SMAD family member 1	TGTGTACTATAC GTATGAGCTTTG TGA	TAACATCCTGGC GGTGGTA
SMAD2	SMAD family member 2	AAAGGGTGGGG AGCAGAATA	GAAGTTCAATCC AGCAAGGAGT
SMAD3	SMAD family member 3	GCATGAGCTTCG TCAAAGG	AATCCAGCAGGG GGTACTG
SMAD4	SMAD family member 4	TGGCCCAGGATC AGTAGGT	CATCAACACCAA TTCCAGCA
SOX9	SRY (sex determining region Y)-box 9	TACCCGCACTTG CACAAC	TCTCGCTCTCGTT CAGAAGTC

**Table 4.** (continued)

TGFB1	transforming growth factor, beta 1	ACTACTACGCCA AGGAGGTCAC	TGCTTGAACTTG TCATAGATTTCG
TGFB2	transforming growth factor, beta 2	GAAGAACTAGAA GCAAGATTTGCA G	TGATCACCCTG GTATATGTGGA
TGFB3	transforming growth factor, beta 3	GCTTTGGACACC AATTACTGC	CCCAGATCCTGT CGGAAGT
TGFB R1	transforming growth factor, beta receptor 1	AAATTGCTCGAC GATGTTCC	CATAATAAGGCA GTTGGTAATCTT CA
TGFB R2	transforming growth factor, beta receptor II	GACCAGAAATTC CCAGCTTCT	CAACGTCTCACA CACCATCTG
TNF	Tumor necrosis factor Precursor (TNF-alpha)	CGGTGCTTGTTT CTCAGC	GCCAGAGGGCTG ATTAGAGA
TWIST 1	twist homolog 1 (Drosophila)	AGCTACGCCTTC TCGGTCT	TCCTTCTCTGGA AACAATGACA
VDR	vitamin D (1,25-dihydroxyvitamin D3) receptor	CTTCTCTGGGGA CTCCTCCT	TGGACGAGTCCA TCATGTCT
HPRT1	hypoxanthine phosphoribosyltransferase 1	TGACCTTGATTT ATTTTGCATACC	CGAGCAAGACGT TCAGTCCT
GDF10	growth differentiation factor 10	TGAATGGATAAT CTCACCGAAA	GTTGGATGGACG AACGATCT
ACTB	actin, beta	GGCCAGGTCATC ACCATT	GGATGCCACAGG ACTCCAT
GAPDH	glyceraldehyde-3-phosphate dehydrogenase	CTCTGCTCCTCCT GTTGAC	ACGACCAAATCC GTTGACTC
G6PD	glucose-6-phosphate dehydrogenase	TCCATCAGTCGG ATACACACA	CACCAGATGGTG GGGTAGAT
Control	polymerase (RNA) II (DNA directed) polypeptide A, 220kDa	CCTGAGTCCGGA TGAAGT	GCCTCCCTCAGT CGTCTCT
Control	polymerase (RNA) II (DNA directed)	GCAAATTCACCA AGAGAGACG	CACGTCGACAGG AACATCAG

**Table 4.** (continued)

Control	polymerase (RNA) II (DNA directed) polypeptide A, 220kDa	TCCGTATTCGCA TCATGAAC	TCATCCATCTTGT CCACCAC
Control	transferrin receptor (p90, CD71)	TGGGTTTTTGTTA CCTTTATGGTT	GGAGGTAACATG CAAATAATGTGA
Control	transferrin receptor (p90, CD71)	TGGGTTTTTGTTA CCTTTATGGTT	GGAGGTAACATG CAAATAATGTGA

## VITA

### BERNA KANKILIÇ

**Address:** Erler Mahallesi Türk Kızılayı Caddesi Toki Deniz Lojmanları Apt No:41 F  
Blok Daire No:14 Etimesgut/Ankara

**Home:** (0312)5538241 **Cell Phone:** (0535)8462398

**E-mail:** uysalberna@yahoo.com

### PERSONAL INFORMATION

**Citizenship:** Turkish Republic

**Birthplace and Date:** Ankara, 30.10.1985

**Marital Status:** Married, 1 child

### EDUCATION

**1999-2002:** TED Ankara College High School

**2002-2006:** Başkent University Faculty of Engineering, Department of Biomedical Engineering

**2006- 2009:** Middle East Technical University, Graduate School of Natural and Applied Sciences Biotechnology Graduate Programme

**2009- ....:** Middle East Technical University Graduate School of Natural and Applied Sciences Biotechnology Doctorate Programme

### INTERNSHIP

**2004-**Gazi University Hospital Biomedical Calibration and Research Center (BİYOKAM), Ankara

**2005-**Philips Health Systems, Ankara

## **WORK EXPERIENCE**

**June 2013-present: R&D Engineer-** FAME-MED MEDICAL. Hacettepe Technopolis 4. R&D Building Floor:2 Office No:52 Çankaya Ankara/Türkiye

## **ATTENDED SEMINARS, EXHIBITIONS and WORKSHOPS**

**2004-BIOMED 2004**, Hacettepe University, Ankara

**2005-EXPOMED, TÜYAP**, İstanbul

**2006-Ankara Engineering Students Community Young Engineer Development Days**, TOBB Economy and Technology University, Ankara

**2006-Cutting Edge Science in Medical Informatics and Medicine**, Middle East Technical University, Ankara

**2007-Workshop on Alternative Methods to Animal Tests**, Hacettepe University, Ankara

**2008-Clinical Orthopaedics and Related Research Writing Workshop**, İstanbul

**2008-BİYOMUT 2008**, Middle East Technical University, Ankara

**2009- Biomaterial- Tissue Compatibility in Tissue Engineering Applications**, Hacettepe University, Ankara

**2009-International Symposium on Biotechnology: Developments and Trends**, Middle East Technical University, Ankara

**2009- XXI. National Turkish Orthopaedics and Traumatology Congress**, Sheraton Hotel, Çeşme, İzmir

**2010- TOTBİD and TOTEK Orthopaedic and Traumatology Basic Sciences Research Workshop**, TSK Rehabilitation Center, Ankara

**2011-TÜBA II. Stem Cell Workshop and VI. Stem Cell Symposium**, Ankara University, Ankara

**2011- BIOMED 2011**, Dedeman Hotel, Ankara

**2014- Advanced Technologies on Health Sciences**, Hacettepe University, Ankara

## PROCEEDINGS IN INTERNATIONAL AND NATIONAL CONGRESSES

1- Uysal B, Bayramlı E, Korkusuz P, Dağdeviren S, Gümüşel B, Korkusuz F; “*Vancomycin-containing Plla Delivery System For The Treatment of Implant Related Chronic Osteomyelitis:An In Vivo Study*”, International Symposium on Biotechnology: Developments and Trends, Middle East Technical University, Ankara

2- Uysal B, Bayramlı E, Korkusuz P, Dağdeviren S, Gümüşel B, Korkusuz F; “*Vankomisin İçeren Plla Taşıyıcı Sisteminin İmplant İlişkili Kronik Osteomyelit Tedavisinde Kullanımı :in-vivo Çalışma*”, XXI. National Turkish Orthopaedics and Traumatology Congress, Sheraton Hotel, Çeşme, İzmir

3- Kankılıç B, Bayramlı E, Bilgiç E, Korkusuz P, Kılıç E, Dağdeviren S, Korkusuz F. Vankomisin içeren PLLA/β-TCP implantla ilişkili osteomyeliti iyileştirmektedir. 20. National Electron Microscopy Congress, Kemer, Antalya

4-Korkusuz F, Dağdeviren S, Uysal B, Korkusuz P, Zeybek D, Akpulat U, Yıldız Y, Kocafe Ç. Gene expression and immunohistochemical changes in skeletal muscles after ovariectomy and TNF-alpha antagonist administration in aged rats. 63<sup>rd</sup> Annual Meeting of the Association of Bone and Joint Surgeons, June 8-12, 2011, Dublin, Ireland (Proceedings book: pp 54-56).

5.Korkusuz F, Kankilic B, Kopru CZ. Material Characterization, Anti-microbiological Action and Biofilm Inhibition Potential of Vancomycin Containing VK1000, 25<sup>th</sup> European Conference on Biomaterials,September 8-12, Madrid, İspanya (Proceedings book: pp 169)

6. Korkusuz F, Kankilic B, Korkusuz P, Dagdeviren S, Bayramli E, Kilic E, Bilgic E. The Biocompatibility of Vancomycin Containing PLLA/β -TCP Composite and Its Role in Implant Related Osteomyelitis, Musculoskeletal Infection Society 23<sup>rd</sup> Open Scientific Meeting, August 2-3, 2013, Philadelphia, USA

7. Korkusuz F , Kankilic B, Korkusuz P, Kopru CZ. In Vitro Assessment of Novel Vancomycin containing VK100 for Cell Culture Studies, Vancomycin Release Studies and Anti-microbiological Action, EORS 2014, July 2-4, 2014, Nantes, France (Proceedings book: pp 48)

## **INTERNATIONAL PUBLICATIONS**
