ABSTRACT. The synthesis of a set of naphthazarin-containing polycyclic conjugated hydrocarbons is described herein. Sequential Diels–Alder reactions on a tautomerized naphthazarin core were employed to access the final conjugated systems. Complete conjugation across the backbone can be achieved through complexation with BF_2 , as observed by ^1H NMR analysis and UV/vis spectroscopy. Precise synthetic control over the degree of oxidation of naphthazarin quinone Diels–Alder adduct **10** is additionally demonstrated, and enables us to direct its subsequent reactivity. Finally, this work serves to demonstrate the potential for naphthazarin as a building block in the synthesis of novel organic electronic materials.

Keywords: naphthazarin / Diels–Alder reactions / phenylene-containing oligoacenes / BF_2 -complex / polycyclic conjugated hydrocarbons / iptycenes

INTRODUCTION

Polycyclic conjugated hydrocarbons are organic small molecules of interest as active materials in electronic and optoelectronic devices. Acenes, such as pentacene and triisopropylsilyl-pentacene (TIPS-pentacene), are among the top performers in organic field effect transistors (OFETs),^{1,2} and while they have achieved significant milestones,³ considerable efforts remain focused on the design and synthesis of new classes of compounds to achieve a desired boost in performance and material stability.

To this end, synthetic chemists have explored structural modifications to the acene core to achieve improved stability, processibility, and electronic properties. Strategies include appending bulky or electron-withdrawing substituents,^{1,4} or including heteroatoms into the core acene unit, such as in the synthesis of anthradithiophenes or azaacenes.^{1,5-13} Other efforts explore a redesign of the bonding architecture of the core molecule, such as through the incorporation of formally antiaromatic cyclobutadiene units, present in [N]phenylenes and phenylene-containing oligoacenes (POAs).¹⁴⁻¹⁹ Alternation of cyclobutadiene units with either benzene ([N]phenylenes) or acene units (POAs) results in localized conjugation along the molecular backbone, which can improve chromophore stability.^{15,16}

Key synthetic approaches to building acene or acene-like small molecules include sequential Diels–Alder reactions,^{16,20,21} cross-coupling methods,^{6,22} or the [2+2+2] methodology used by Vollhardt and coworkers to synthesize extended [N]phenylenes.¹⁵

In this study, we capitalize on the ability of naphthazarin (1,4-dihydroxy-5,8-naphthaquinone)²³⁻²⁵ to act as a bifunctional Diels–Alder reagent to access new iptycene and POA molecules in a convergent manner. Examples of target structures are presented in Figure 1. Naphthazarin has the ability to react twice as a dienophile,²⁶

1
2
3 which can be achieved *via* oxidation and tautomerization of the initial Diels–Alder
4 adduct to unmask a second dienophile equivalent on the opposite side of the
5 naphthazarin core. This makes it an appealing building block to convergently
6 synthesize multi-ring systems. Historically, naphthazarins have been utilized
7 predominantly in the construction of anthracyclines,^{23–27} and in this study we intend
8 to demonstrate its further potential as a useful building block in the synthesis of
9 organic electronic materials.

16
17

18 We also demonstrate that the naphthazarin-derived Diels–Alder adducts
19 presented herein can coordinate to two BF₂ groups to form conjugated electron-
20 deficient complexes.^{28,29} These types of materials may prove useful as electron-
21 transporting materials and n-type semiconductors.^{28,29} To this end, we report the
22 synthesis and spectroscopic properties of a set of triptycene, pentiptycene, and POA
23 naphthazarin-based structures (Figure 1), as well as a proof-of-concept demonstration
24 of their complexation with BF₃-OEt₂.

RESULTS AND DISCUSSION

Synthesis of naphthazarin triptycene derivatives 7a–d. Triptycene compounds 7a–
d were accessed through an initial [4+2] Diels–Alder cycloaddition reaction of

naphthazarin (**5**) with a corresponding anthracene (**4a–d**) to furnish mono-cycloadducts **6a–d**, followed by oxidation to the target triptycene intermediates **7a–d** (Scheme 1).

Scheme 1. Synthesis of naphthazarin triptycenes **7a–d** and pentiptycenes **1a–d**.

Formation of cycloadducts **6a–d** occurred in moderate to good yields (20–80%). Oxidation of **6a–d** in the presence of air and excess of KO^tBu produced naphthazarin triptycenes **7a–d** in nearly quantitative yields. Reactivity of the anthracene precursors with naphthazarin varies, and we observe anthracene **4d** reacting in the highest yield, likely due to its more electron-rich character relative to the other selected anthracenes.

Single crystals of **6b**, **7a**, and **8a** suitable for X-ray crystallography were obtained by slow evaporation from CH₂Cl₂/*n*-hexane at 25 °C (Figures 2 and S1–3, Supporting Information). Although DFT calculations support the tetrasubstituted quinone tautomer **7a** as the more thermodynamically stable isomer,²³ the crystal structure of **7a** was elucidated as tautomer **7a-T**. Calculations at the B3LYP/6-31G(d) level showed that the energy difference between structures **7a** and **7a-T** is 1.05

1
2
3 kcal/mol. (For further details on the computational investigations, see the Supporting
4
5 Information.)

Synthesis of naphthazarin pentiptycene compounds 1a–d. Naphthazarin-based cycloadducts are known to tautomerize to expose the quinone-based dienophile (**7-T**), which can undergo a second cycloaddition reaction with a diene.²⁶ Upon heating, we observed a second equivalent of **4a–d** to undergo a [4+2] cycloaddition with **7a–d** to yield double-cycloadducts **8a–d** in 31–61% yields (Scheme 1).

Similar to the conversion observed from **6a–d** to **7a–d**, we found that KO^tBu enolized cycloadducts **8a–c** and, in the presence of air, cleanly transformed them into **1a–c** in excellent yield. This method of oxidation is very mild, and enables us to access a portfolio of functionalized naphthazarin pentiptycenes³⁰ with varying degrees of internal free volume.³¹ Isolation of pentiptycene **1d**, however, was not possible. Although we observed characteristic changes in color that signified conversion of **8d** to **1d** (from yellow to dark blue upon addition of KO^tBu, then to dark red after work-up), our attempts to isolate **1d** were unsuccessful as a result of the limited solubility and unexpected decomposition of the product. (See Figure S46 for the UV/vis spectrum of the final reaction mixture.)

Synthesis of naphthazarin phenylene-containing-oligoacene compounds 2a–b and 3. We next hypothesized that the Diels–Alder reactivity of the naphthazarin core

1
2
3 could be extended to a synthetic approach to access novel POAs.^{16,19} Naphthazarin
4 presents an opportunity to incorporate an electron-deficient acene unit into the POA
5 backbone, in particular when complexed with BF₂. The naphthazarin motif also
6 provides functional handles for further synthetic manipulation or complexation to
7 metals^{32,33} and boron moieties.^{28,29}
8
9

10
11 To synthesize naphthazarin-derived POAs, we utilized diene **9**, which can be
12 accessed in two steps according to literature procedures.^{16,19,34–39} Diene **9** was reacted
13 with naphthazarin (**5**) to furnish mono-adduct **10** in 49% yield (Scheme 2).
14 Interestingly, X-ray crystallographic analysis of compound **10** shows a *trans*
15 arrangement of the hydrogen atoms located at the adduct site (Figure S4 in the SI).
16 This is in stark contrast to the expected stereochemistry of Diels–Alder cycloaddition
17 products, as the *exo* and/or *endo* product is often observed, and the resultant
18 placement of hydrogen atoms in space depends on this product ratio.⁴⁰ The *trans*
19 relationship in the crystal structure of **10** could signify that the operative mechanism
20 of reaction is, in fact, step-wise instead of a true concerted cycloaddition.
21 Alternatively, the *trans* relationship may be due to epimerization resulting from
22 enolization at the α -carbon that occurs following a conventional *cis* [4+2]
23 cycloaddition. An explanation is that the hydrogen-bonding between the hydroxyl
24 groups and the ketones of the naphthazarin core increases the likelihood of
25 enolization at the α -carbons, and, for sterically-induced reasons, the hydrogen atoms
26 end up *trans* to one another. While we observe a *trans* relationship for compound **10**
27 by X-ray analysis, we detect the presence of three isomers by NMR (Figure S84 in the
28 SI), leading us to conclude that the *trans* product is likely present alongside the *endo*
29 and *exo* adducts.

With **10** in hand, we next unmasked dienophile **11-T** to enable further Diels–Alder reactivity (Scheme 3), and found an interesting dependence on the equivalents of KO^tBu used. By adjusting the amount of KO^tBu and reaction time, we were able to effectively tune the level of oxidation to produce either partially-oxidized product **11** or fully-oxidized product **12** (Scheme 2).²⁶ This capability is significant, as we found that only partially-oxidized **11** is able to further tautomerize *in situ* to produce **11-T**, which brandishes an external-facing dienophile. Fully-oxidized **12** contains an additional aromatic ring that stabilizes and “locks” the internal 9,10-quinone in place. Here, we found that when mono-adduct **10** was reacted with only three equivalents of KO^tBu for a short period of time (five minutes), we were able to achieve the partially oxidized product **11** in 52% yield. When reacted in significant excess and for extended periods of time, the fully oxidized product **12** became the major or sole product (18 equiv., 78% yield). X-ray crystal structures of **10–12** are shown in Figures S4–S6 in the SI.

Fully-oxidized **12** can be converted to target compound **2a** in 84% yield through hydrolysis of the bridging oxygen when exposed to an acidic solution of hydrochloric acid in chloroform and isopropyl alcohol.⁴¹ Poor solubility of **2a**

prevented acquisition of a ^{13}C NMR spectrum. An alternative target was found in **2b**, which proved more soluble than **2a**, and can be obtained through conversion from **12** (58% yield) or from **2a** (49% yield) using *p*-TsOH/Ac₂O.

Scheme 3. Targeted synthesis of POA double-adduct **14**.

We next induced tautomerization of partially-oxidized **11**, and reacted the *in situ*-generated **11-T** dienophile with diene **9** for a second cycloaddition reaction. Overall, Diels–Alder reaction of **11-T** with diene **9** and subsequent oxidation with KO^tBu in the presence of air yielded **13** in 13% yield. Unfortunately, multiple attempts to convert **13** to the final symmetrical POA double-adduct **14** failed. The challenges we faced in isolating **14** were likely due to poor solubility, as was similarly encountered with pentyptycene **1d** and POA mono-adduct **2a**. We did observe consumption of **13** upon exposure to acid and were able to detect **14** by MALDI-TOF mass spectrometry (see Figure S112). However, the reaction largely produced a substantial amount of insoluble material that we were unable to isolate for full characterization.

To circumvent these problems, we redesigned our synthetic plan and instead targeted compound **3** (Scheme 4). We hypothesized that the non-planar triptycene end-group of **3** would eliminate the aforementioned solubility and aggregation issues.³¹ We attempted to react the *in situ* generated **11-T** dienophile with one equivalent of anthracene **4a**, but were only able to observe trace amounts of product by TLC.

Scheme 4. Targeted synthesis of iptycene-POA **3**.

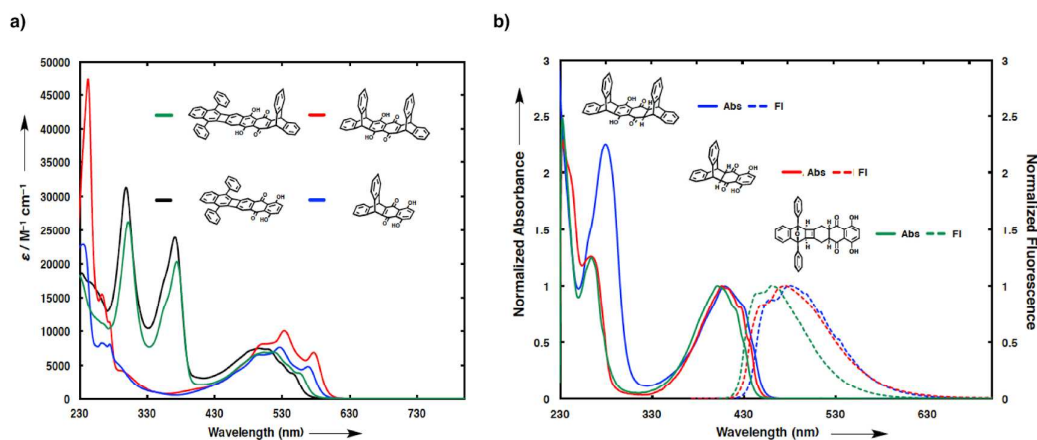

Due to the insufficient reactivity of **11-T**, we sought to access target compound **3** by reversing our synthetic strategy. To this end, we were able to successfully react **7a** with diene **9** to yield double-adduct POA-iptycene **15** in 30% yield over two steps. The final product **3** could be accessed under acidic conditions and collected in 75% yield as a dark-orange product. This compound proved reasonably soluble in 1,1,2,2-tetrachloroethane and could be characterized, but was exemplary of the solubility challenges faced in trying to access the symmetrical double POA adduct.

Spectroscopic Properties of mono- and double-adducts

The UV/vis spectra of four selected naphthazarin derivatives **1a**, **2a**, **3**, and **7a** are shown in Figure 3a (See Figures S12–22 in the SI for the UV/vis spectra of all compounds). The UV/vis spectra of **1a**, **2a**, **3**, and **7a** are characteristic of naphthazarins, showing vibronically coupled bands with significant fine structures at lower energy. The deep red-colored compound **7a** exhibits a fine-structure absorption band at $\lambda_{\text{max}} = 568 \text{ nm}$ (2.18 eV, $\epsilon = 4800 \text{ M}^{-1} \text{ cm}^{-1}$). The additional triptycene unit in **1a** caused a bathochromic shift of 8 nm [$\lambda_{\text{max}} = 576 \text{ nm}$ (2.15 eV, $\epsilon = 6900 \text{ M}^{-1} \text{ cm}^{-1}$)].

Vertical optical transitions were calculated on the optimized structures of **7a** and **1a** by time-dependent density functional theory (TD-DFT), using the software package Gaussian 03 (See Supporting Information for further details).⁴² The computed transition energies in both cases are slightly lower than the experimental values (Table S1 and S2). The spectra of mono and double POA-naphthazarin compounds **2a** and **3** display low energy bands at $\lambda_{\text{max}} = 551 \text{ nm}$ (2.25 eV, $\epsilon = 3180 \text{ M}^{-1} \text{ cm}^{-1}$) and $\lambda_{\text{max}} = 557 \text{ nm}$ (2.23 eV, $\epsilon = 3745 \text{ M}^{-1} \text{ cm}^{-1}$), respectively. Electrochemical analysis of these compounds reveals two quasireversible waves, consistent with literature studies (see Figure S114 and Table S5).^{43,44}

Figure 3. (a) UV/vis spectra of selected compounds **1a** (red line), **2a** (black line), **3** (green line), and **7a** (blue line) in CH_2Cl_2 at 298 K. (b) Normalized absorbance (solid lines) and fluorescence (dashed lines) spectra of selected compounds **6a** (red lines, $\lambda_{\text{ex}} = 355 \text{ nm}$), **8a** (blue lines, $\lambda_{\text{ex}} = 355 \text{ nm}$), and **10** (green lines, $\lambda_{\text{ex}} = 375 \text{ nm}$) in CH_2Cl_2 at 298 K.

Upon analysis, some of the compounds synthesized in this study showed interesting fluorescent properties (Table 1 and Figure 3b). The unoxidized cycloaddition adducts (compounds **6a–d**, **8a–d**, and **10**) showed strong blue fluorescence with high quantum yields ($\Phi_F = 0.58–0.91$). Though fluorescent Diels–Alder adducts of naphthazarin have been reported,^{45,46} the strong fluorescence of **6a–d**, **8a–d**, and **10** was unexpected due to the lack of π -conjugation across the backbone. This strong blue emission was observed across the series, suggesting it may be due to the enolizable nature or the hydrogen-bonding capabilities of the unoxidized naphthazarin adduct.

Table 1. Photophysical characterization of emissive compounds synthesized. All measurements were performed in CH_2Cl_2 ($\lambda_{\text{ex}} = 375 \text{ nm}$).

3 **Investigation of BF₂-complexation with the naphthazarin-cores** Complexation of
4
5 BF₃-OEt₂ with the naphthazarin core of various synthesized compounds renders the
6
7 molecules fully conjugated, and was explored for potential n-type semiconducting
8
9 applications.
10

11
12 Representative complexation studies were conducted with ¹H NMR, UV/vis and
13
14 mass spectroscopy. For example, we were able to observe the conversion of
15
16 compound **1a** to **BF₂-1a** following the addition of BF₃-OEt₂ to **1a** in CH₂Cl₂. The
17
18 product could be isolated through precipitation and was analyzed by ¹H NMR as
19
20 shown in Figure 4. Here, we observe the disappearance of the hydroxyl peak around
21
22 12 ppm, and see a distinct shift in the aromatic and bridgehead peaks upon
23
24 complexation. Finally, a mixture of the two products clearly demonstrates the
25
26 appearance of two discrete molecules in solution. The structure of **BF₂-1a** was also
27
28 confirmed by HR-ESI-MS (*m/z* calcd for C₃₈H₂₀B₂F₄O₄⁻: 638.1518; found: 638.1503
29
30 [M]⁻) Susceptibility to hydrolysis was consistent with previous reports in the
31
32 literature.^{28,29} Presumably due to moisture present in the air, hydrolysis was observed
33
34 for **BF₂-1a** to occur in CDCl₃ over 1-2 hours, precluding ¹³C NMR analysis.
35
36

During the reaction of compound **1a** with $\text{BF}_3\text{-OEt}_2$, the solution changed from dark red to dark purple, and was observed by UV/vis spectroscopy as a shift in absorbance bands from ~ 533 nm to ~ 561 nm (Figure 5). This red-shifted absorption maximum of **BF₂-1a** reveals the generation of a fully conjugated structure through BF_2 chelation. Similar spectral changes were observed with **BF₂-1b** and **BF₂-1c** (see Figures S39–42 in the SI for the UV/vis spectra of **BF₂-1b** and **BF₂-1c**). In studying this complexation spectroscopically for **BF₂-2a** and **BF₂-3**, our characterization attempts were hampered by the limited solubility of substrates **2a** and **3**, similar to that observed in literature.^{28,29} Despite this challenge, we were still able to observe a color change from orange to dark blue upon addition of $\text{BF}_3\text{-OEt}_2$, which was similar to that observed for the **BF₂-1** series (See Figures S43–45 in the SI for the UV/vis spectra of **BF₂-2a** and **BF₂-3**).

Figure 5. UV/vis spectra of compound **1a** (black line) and **BF₂-1a** (blue line) in CH_2Cl_2 at 298 K.

CONCLUSION

In conclusion, a selection of naphthazarin-containing polycyclic conjugated hydrocarbon molecules were synthesized and characterized, and may find utility in optoelectronic and other electronic applications. The molecular design includes 1) iptycene wings to add free space around the chromophores for better solubility, and 2) structural motifs of POAs to achieve improved stability. Successful coordination with BF_2 as a proof-of-concept reveals the potential for new conjugated n-type electronic materials or expanded coordination complex structures, such as conducting metallopolymers.

Experimental Section

General. Reagents were purchased as reagent grade and used without further purification. All solvents were of ACS reagent grade or better. Toluene was passed through a solvent purification system *via* columns of activated alumina, and stored over 3 Å sieves. Reactions in the absence of air and moisture were performed in oven-dried glassware under Ar or N_2 atmosphere. Flash column chromatography (FC) was performed using SiO_2 (60 Å, 230–400 mesh, particle size 0.040–0.063 mm) at 25 °C with a head pressure of 0.0–0.5 bar. The used solvent compositions are reported individually in parentheses. Analytical thin layer chromatography (TLC) was performed on sheets coated with silica gel (200 μm, IB-F). Visualization was achieved using UV light (254 or 366 nm). Evaporation *in vacuo* was performed at 25–60 °C and 900–10 mbar. Reported yields refer to spectroscopically and chromatographically pure compounds that were dried under high vacuum (0.1–0.05 mbar) before analytical characterization. ^1H and ^{13}C nuclear magnetic resonance (NMR) spectra were recorded at 500 or 400 MHz (^1H) and 125 or 100 MHz (^{13}C),

1
2
3 respectively. Chemical shifts δ are reported in ppm downfield from tetramethylsilane
4
5 using the residual solvent signals as an internal reference (CDCl₃: $\delta_{\text{H}} = 7.26$ ppm, δ_{C}
6
7 = 77.16 ppm / Cl₂CDCDCl₂: $\delta_{\text{H}} = 6.0$ ppm, $\delta_{\text{C}} = 73.78$ ppm). For ¹H NMR, coupling
8
9 constants J are given in Hz and the resonance multiplicity is described as s (singlet), d
10
11 (doublet), t (triplet), q (quartet), quint (quintet), sext (sextet), sept (septet), m
12
13 (multiplet), and br. (broad). All spectra were recorded at 298 K. High-resolution mass
14
15 spectrometry (HRMS) was performed by the MS-service of the MIT Department of
16
17 Chemistry Instrumentation Facility using an Ion Cyclotron Resonance Mass
18
19 Spectrometer with either electrospray (ESI) or Direct Analysis in Real Time (DART)
20
21 as the ionization technique. Where noted, additional mass spectra were obtaining
22
23 using Matrix-Assisted Laser Desorption/Ionization-Time-of-Flight (MALDI-TOF),
24
25 by depositing samples directly onto the target without a matrix. UV/vis spectroscopy
26
27 was recorded on a UV/vis spectrophotometer and corrected for background signal
28
29 with a solvent-filled cuvette. Fluorescence spectra were measured using right-angle
30
31 detection. Absolute quantum yield measurements were carried out using an
32
33 integrating sphere, which was coupled to the fluorometer *via* an optical fiber bundle.
34
35 Samples were excited with a 450W Xenon short arc lamp and fluorescence was
36
37 detected with a detector. All photophysical measurements were performed with
38
39 spectral grade dichloromethane.
40
41
42

Compound 7a

6a (110 mg, 0.299 mmol), KO^tBu (201 mg, 1.79 mmol): **7a**, red solid (107 mg, 98% yield). Mp: 317–319 °C. R_f = 0.75 (CH₂Cl₂). ¹H NMR (400 MHz, CDCl₃): δ 12.61 (s, 2H), 7.48 (br. dd, 4H, *J* = 5.3, 3.3 Hz), 7.09 (s, 2H), 7.06 (br. dd, 4H, *J* = 5.3, 3.3 Hz), 6.04 ppm (s, 2H). ¹³C NMR (101 MHz, CDCl₃): δ 175.2, 167.0, 152.9, 143.6, 132.7, 125.9, 124.6, 111.4, 47.6 ppm. UV/vis (CH₂Cl₂): λ_{max} (ε) = 235 (22860), 262 (8250), 274 (8070), 496 (6520), 526 (7610), 568 nm (4800 M⁻¹ cm⁻¹). HR-DART-MS: *m/z* calcd for C₂₄H₁₅O₄⁺: 367.0965; found: 367.0954 [M + H]⁺.

Compound 7b

6b (210 mg, 0.495 mmol), KO^tBu (333 mg, 2.97 mmol): **7b**, red solid (159 mg, 76% yield). Mp: 315–317 °C. R_f = 0.83 (CH₂Cl₂). ¹H NMR (400 MHz, CDCl₃): δ 12.64 (s, 2H), 7.28 (s, 4H), 7.09 (s, 2H), 5.92 (s, 2H), 2.20 ppm (s, 12H). ¹³C NMR (101 MHz, CDCl₃): δ 175.7, 166.4, 153.7, 141.5, 133.7, 132.4, 125.8, 111.4, 46.7, 19.6 ppm. UV/vis (CH₂Cl₂): λ_{max} (ε) = 245 (14350), 263 (15200), 283 (10700), 489 (4810), 526 (5610), 567 nm (3570 M⁻¹ cm⁻¹) HR-DART-MS: *m/z* calcd for C₂₈H₂₃O₄⁺: 423.1591; found: 423.1573 [M + H]⁺.

Compound 7c

6c (40 mg, 0.083 mmol), KO^tBu (56 mg, 0.499 mmol): **7c**, red solid (39 mg, 99% yield). Mp: 115–117 °C. R_f = 0.58 (DCM). ¹H NMR (400 MHz, CDCl₃): δ 12.62 (s, 2H), 7.50 (s, 2H), 7.39 (d, 2H, *J* = 7.9 Hz), 7.09 (s, 2H), 7.06 (d, 2H, *J* = 7.9 Hz), 5.97 (s, 2H), 1.26 ppm (s, 18H). ¹³C NMR (101 MHz, CDCl₃): δ 176.4, 165.9, 153.7, 149.1, 143.7, 140.8, 132.3, 124.0, 122.4, 121.9, 111.5, 47.5, 34.8, 31.6 ppm. UV/vis (CH₂Cl₂): λ_{max} (ε) = 237 (13700), 260 (7590), 278 (6480), 496 (3940), 526 (4590), 568 nm (2960 M⁻¹ cm⁻¹). HR-DART-MS: *m/z* calcd for C₃₂H₃₁O₄⁺: 479.2217; found: 479.2215 [M + H]⁺.

Compound 7d

6d (100 mg, 0.170 mmol), KO^tBu (114 mg, 1.02 mmol): **7d**, red solid (85 mg, 85% yield). Mp: >350 °C R_f = 0.84 (CH₂Cl₂). ¹H NMR (400 MHz, CDCl₃): δ 12.62 (s, 2H), 7.39 (br. s, 4H), 7.05 (br. s, 2H), 5.88, (s, 2H), 1.62 (s, 8H), 1.24 ppm (s, 24H). ¹³C NMR (101 MHz, CDCl₃): δ 177.8, 164.6, 154.0, 142.2, 140.6, 131.7, 122.6, 111.6, 47.1, 35.2, 34.5, 32.1, 32.0 ppm. UV/vis (CH₂Cl₂): λ_{max} (ε) = 240 (16870), 273 (12120), 284 (12600), 489 (6370), 526 (7630), 568 nm (4830 M⁻¹ cm⁻¹). HR-DART-MS: *m/z* calcd for C₄₀H₄₂O₄⁺: 587.3078; found: 587.3083 [M + H]⁺.

Double-adduct pentiptycene synthesis: Compounds 8a–d

Compound **7a–d** (1 equiv.) and the appropriate anthracene **4a–d** (1 equiv.) were added to a flame-dried Schlenk flask with stir bar, and were dissolved in the minimal amount of anhydrous toluene (<1 mL). The headspace was purged with argon for 30 minutes, then heated to reflux overnight (111 °C). The solvent that remained was concentrated *in vacuo*. FC (SiO₂; 100% *n*-hexanes to 100% CH₂Cl₂).

Compound 8a

7a (36 mg, 0.098 mmol), **4a** (17.5 mg, 0.098 mmol): **8a**, yellow solid (22 mg, 41% yield). Mp: 190–192 °C (decomp). R_f = 0.89 (CH₂Cl₂). ¹H NMR (400 MHz, CDCl₃): δ 12.75 (s, 2H), 7.50 – 7.35 (m, 6H), 7.17 (quasi t, 2H, *J* = 4.3 Hz), 7.12 (quasi t, 2H, *J* = 4.3 Hz), 7.06 – 7.01 (m, 2H), 7.01 – 6.97 (m, 2H), 6.91 – 6.86 (m, 2H), 5.99 (s, 2H), 5.05 (s, 2H), 3.27 ppm (s, 2H). ¹³C NMR (101 MHz, CDCl₃): δ 201.9, 151.2, 145.5, 144.1, 143.8, 142.1, 140.0, 126.9, 126.7, 125.74, 125.72, 124.6, 124.4, 124.3, 124.0, 113.1, 49.5, 48.8, 47.6 ppm. UV/vis (CH₂Cl₂): λ_{max} (ε) = 269 (13378), 408 (5423), 429 nm (4503 M⁻¹ cm⁻¹). HR-DART-MS: *m/z* calcd for C₃₈H₂₃O₄⁻: 543.1602; found: 543.1620 [M – H]⁻.

Compound 1b

8b (94 mg, 0.143 mmol), KO^tBu (96 mg, 0.859 mmol): **1b**, red solid (51 mg, 54% yield). Mp: >350 °C. R_f = 0.80 (CH₂Cl₂). ¹H NMR (400 MHz, CDCl₃): δ 12.87 (s, 2H), 7.18 (s, 8H), 5.82 (s, 4H), 2.13 ppm (s, 24H). ¹³C NMR (101 MHz, CDCl₃): δ 169.0, 151.6, 141.7, 133.5, 125.7, 110.1, 46.7, 19.6 ppm. UV/vis (CH₂Cl₂): λ_{max} (ε) = 248 (30200), 273 (20415), 283 (17150), 502 (7500), 534 (9160), 577 nm (6420 M⁻¹ cm⁻¹). HR-DART-MS: *m/z* calcd for C₄₆H₃₉O₄⁺: 655.2843; found: 655.2856 [M + H]⁺.

Compound 1c

8c (111 mg, 0.144 mmol), KO^tBu (97 mg, 0.866 mmol): **1c**, red solid (50 mg, 45% yield). Mp: 264–266 °C. R_f = 0.97 (CH₂Cl₂). ¹H NMR (400 MHz, CDCl₃): δ 12.95 (s, 2H), 7.46 (s, 4H), 7.36 (br. d, 4H, *J* = 7.7 Hz), 7.03 (br. d, 4H, *J* = 7.7 Hz), 5.94 (s, 4H), 1.25 ppm (s, 36H). ¹³C NMR (101 MHz, CDCl₃): δ 169.2, 151.6, 148.9, 143.8, 140.9, 123.8, 122.3, 121.7, 110.1, 47.5, 34.8, 31.6 ppm. UV/vis (CH₂Cl₂): λ_{max} (ε) = 245 (41075), 267 (19620), 278 (15230), 504 (8130), 533 (10010), 577 nm (6910 M⁻¹ cm⁻¹). HR-ESI-MS: *m/z* calcd for C₅₄H₅₅O₄⁺: 767.4095; found: 767.4088 [M + H]⁺.

Synthesis of the POA series**Compound 10**

Naphthazarin (**5**) (100 mg, 0.526 mmol) and diene **9** (238 mg, 0.684 mmol) were added to either an oven-dried pressure tube or flame-dried Schlenk flask with stirrer bar, and were dissolved in the minimal amount of anhydrous toluene (1–2 mL). The headspace was purged with argon for 30 minutes, then heated to reflux overnight (111 °C). The solvent was concentrated *in vacuo*. Gravity column chromatography (SiO₂: CH₂Cl₂) or FC (SiO₂; 100% *n*-hexanes to 100% CH₂Cl₂) yielded 138 mg (49% yield) of a yellow solid. Note that while the highest yields were obtained when carried out in

1
2
3 a pressure tube, similar yields are obtained when carried out under refluxing
4
5 conditions. Note also that by NMR we observe 1:0.20:0.20 ratio of isomers, based on
6
7 the hydroxyl peaks. The ^1H NMR integrations are calculated such that hydroxyl peaks
8
9 in 11.94–11.79 integrate to a total of 2H. Mp: 301–303 °C. $R_f = 0.32$ (DCM).

10
11 ^1H NMR (400 MHz, CDCl_3): δ 11.94 (s, 0.28 H), 11.90 (s, 0.28 H), 11.78 (s, 1.43 H),
12
13 7.66 (m, 4 H), 7.44 (m, 6 H), 7.20 (s, 2 H), 7.12 (m, 2 H), 6.95 (m, 2 H), 3.47 (m, 2
14
15 H), 3.13 (m, 2 H), 2.20 (m, 4 H). ^{13}C NMR (101 MHz, CDCl_3): δ 203.5, 202.7, 155.3,
16
17 155.2, 155.1, 148.1, 140.7, 140.5, 137.2, 137.1, 128.7, 128.62, 128.57, 128.51, 128.4,

59
60

(ϵ) = 279 (7718), 482 (6380), 511 (7071), 550 nm (4181 M⁻¹ cm⁻¹). HR-DART-MS: m/z calcd for C₃₆H₂₅O₅⁺: 537.1697; found: 537.1684 [M + H]⁺.

Compound 12

To a 25 mL round-bottom flask was added **10** (105 mg, 0.195 mmol) and KO^tBu (394 mg, 3.51 mmol) in 20 mL THF. After stirring under ambient conditions for 1–3 h, the blue reaction mixture was poured over NH₄Cl (aq) and extracted with EtOAc. The organic layer was dried with MgSO₄, filtered and evaporated. FC (SiO₂; CH₂Cl₂) gave **12** as an orange solid (81 mg, 78% yield). Mp: 304–305 °C. R_f = 0.47 (CH₂Cl₂). ¹H NMR (400 MHz, CDCl₃): δ 12.80 (s, 2H), 7.75 – 7.70 (m, 6H), 7.56 – 7.52 (m, 4H), 7.49 – 7.44 (m, 2H), 7.22 (dd, 2H, J = 5.4, 3.0 Hz), 7.19 (s, 2H), 7.11 (dd, 2H, J = 5.4, 3.0 Hz), 4.34 ppm (s, 2H). ¹³C NMR (101 MHz, CDCl₃): δ 187.1, 157.7, 151.0, 147.5, 135.7, 134.5, 129.2, 128.9, 128.6, 127.5, 126.8, 121.2, 119.7, 112.5, 89.0, 55.7 ppm. UV/vis (CH₂Cl₂): λ_{\max} (ϵ) = 275 (38000), 486 nm (8080 M⁻¹ cm⁻¹). HR-DART-MS: m/z calcd for C₃₆H₂₃O₅⁺: 535.1540; found: 535.1541 [M + H]⁺.

Compound 2a

In a flame-dried 25 mL Schlenk flask, compound **12** (21 mg, 0.039 mmol) was dissolved in 1:1 isopropyl alcohol-CHCl₃ (0.5 mL each). Concentrated HCl (0.2 mL) was added slowly to the solution under argon. The solution was heated to 80 °C for 4 hours. The product was washed with deionized water and extracted with CH₂Cl₂, then concentrated *in vacuo*. The product was washed with hexanes, then filtered and dried overnight under vacuum, affording **2a** as a red solid (17 mg, 84% yield). Mp: > 350 °C. R_f = 0.53 (CH₂Cl₂). ¹H NMR (400 MHz, CDCl₃): δ 12.88 (s, 2H), 7.87 (dd, 2H, J = 6.3, 3.4 Hz), 7.65 – 7.60 (m, 8H), 7.56 (s, 2H), 7.55 – 7.50 (m, 2H), 7.37 (dd, 2H, J = 6.3, 3.4 Hz), 7.27 ppm (s, 2H). UV/vis (CH₂Cl₂): λ_{abs} (ϵ) = 298 (31300), 370

(23900), 511 (7270), 551 nm (3180 M⁻¹ cm⁻¹). HR-DART-MS: *m/z* calcd for C₃₆H₂₁O₄⁺: 517.1434; found: 517.1422 [M + H]⁺.

Compound 2b

In a flame-dried 25 mL Schlenk flask, compound **12** (154 mg, 0.288 mmol) was dissolved in 10 mL acetic anhydride with *p*-TsOH crystals (694 mg, 4.0 mmol). The solution was heated to 120 °C for 12 hours. The product was precipitated by pouring solution over ice, and adding water until a solid precipitate formed. The product was filtered and dried overnight under vacuum, affording **2b** as an orange solid (100 mg, 58% yield). Mp: 285–287 °C. R_f = 0.33 (CH₂Cl₂). ¹H NMR (400 MHz, CDCl₃): δ 7.84 (dd, 2H, *J* = 6.2, 3.4 Hz), 7.62 – 7.57 (m, 8H), 7.55 – 7.48 (m, 2H), 7.40 – 7.32 (m, 6H), 2.45 ppm (s, 6H). ¹³C NMR (101 MHz, CDCl₃): δ 183.3, 169.6, 155.7, 148.1, 142.2, 136.1, 135.7, 135.2, 131.5, 130.9, 129.6, 129.1, 128.5, 127.6, 127.4, 125.8, 115.3, 21.3 ppm. UV/vis (CH₂Cl₂): λ_{max} (ε) = 299 (41950), 368 (39395), 463 nm (2878 M⁻¹ cm⁻¹). HR-DART-MS: *m/z* calcd for C₄₀H₂₅O₆⁺: 601.1646; found: 601.1643 [M + H]⁺.

Compound 13

11 (32 mg, 0.060 mmol) and diene **9** (21 mg, 0.060 mmol) were added to a flame-dried Schlenk flask with stir bar, and were dissolved in the minimal amount of anhydrous toluene (1–2 mL). The headspace was purged with argon for 30 minutes, then heated to reflux overnight (111 °C). The solvent was concentrated *in vacuo*. KO^tBu (121 mg, 1.07 mmol) and 20 mL THF were added to the flask, and the reaction was allowed to stir 1–3 h under ambient conditions. The blue reaction mixture was then poured over NH₄Cl (aq) and extracted with EtOAc. The organic layer was dried with MgSO₄, filtered and evaporated. Gravity column chromatography (SiO₂: CH₂Cl₂) gave **13** (7 mg, 13% yield) as an orange solid. Mp:

1
2
3 315–317 °C. $R_f = 0.75$ (CH_2Cl_2). ^1H NMR (400 MHz, CDCl_3): δ 15.03 (s, 2H), 7.80
4 (s, 4H), 7.75 – 7.71 (m, 8H), 7.52 (t, 8H, $J = 7.4$ Hz), 7.47 – 7.42 (m, 4H), 7.20 (dd,
5 4H, $J = 5.4, 3.0$ Hz), 7.09 (dd, 4H, $J = 5.4, 3.0$ Hz), 4.34 ppm (s, 4H). ^{13}C NMR (100
6 MHz, CDCl_3): δ 179.6, 172.7, 148.8, 147.8, 135.9, 133.3, 128.8, 128.5, 127.4, 126.9,
7 120.1, 119.7, 113.6, 105.8, 89.2, 55.5 ppm. UV/vis (CH_2Cl_2): λ_{max} (ϵ) = 285 (76508),
8 491 (24618), 462 (15226), 315 (24907), 526 nm (22821 $\text{M}^{-1} \text{cm}^{-1}$). HR-DART-MS:
9 m/z calcd for $\text{C}_{62}\text{H}_{38}\text{O}_6\text{Na}^+$: 901.2561; found: 901.2549 $[\text{M} + \text{Na}]^+$.

18 **Compound 14**

20 In a flame-dried 25 mL Schlenk flask, compound **13** (21 mg, 0.039 mmol) was
21 dissolved in 1:1 isopropyl alcohol- CHCl_3 (0.5 mL each). Concentrated HCl (0.2 mL)
22 was added slowly to the solution under argon. The solution was heated to 80 °C for
23 four hours. The product was washed with deionized water and extracted with CH_2Cl_2 ,
24 then concentrated *in vacuo*, affording insoluble dark colored solid. Poor solubility and
25 decomposition precluded further characterization beyond mass detection by MALDI-
26 TOF. MALDI-TOF-MS: m/z calcd for $\text{C}_{62}\text{H}_{34}\text{O}_4^+$: 842.24, found 842.08 $[\text{M}]^+$ (See
27 S112–113. for mass spectrum).

38 **Iptycene-POAs**

40 **Compound 15**

42 **7a** (90 mg, 0.246 mmol) and diene **9** (86 mg, 0.246 mmol) were added to a flame-
43 dried Schlenk flask with stir bar, and were dissolved in the minimal amount of
44 anhydrous toluene (1–2 mL). The headspace was purged with argon for 30 minutes,
45 then heated to reflux overnight (111 °C). The solvent was concentrated *in vacuo*.
46 KO^tBu (496 mg, 4.42 mmol) and 20 mL THF were added to the flask, and the
47 reaction was allowed to stir 1–3 h under ambient conditions. The blue reaction
48 mixture was then poured over NH_4Cl (aq) and extracted with EtOAc. The organic

5 6 **ACKNOWLEDGMENTS**

7
8 This work was supported by the National Science Foundation through award DMR-
9 1410718, and Graduate Research Fellowships (Grant No. 122374 (G. D. G. and S. P.
10 L.) Any opinion, findings, and conclusions or recommendations expressed in this
11 material are those of the authors(s) and do not necessarily reflect the views of the
12 National Science Foundation. This was also supported by an Early Postdoc Mobility
13 fellowship from the Swiss National Science Foundation (SNF) (C. D.). The authors
14 thank Dr. Peter Müller and Dr. Jonathan Becker for collecting and solving X-ray
15 structure data and Dr. Tristan Reekie for reviewing the manuscript.
