A MASTER THESIS

SUBMITTED TO THE DEPARTMENT OF CIVIL ENGINEERING
AND THE COMMITTEE ON THE FACULTY OF ENGINEERING
OF THE MIDDLE EAST TECHNICAL UNIVERSITY
IN PARTIAL FULFILLMENT OF THE REQUIREMENTS
FOR THE DEGREE OF
MASTER OF SCIENCE

By Taha Aksoy April 1972 TO NILGUN

~

1, 44521 - 1011 - 1

I certify that I have read this thesis and that in my opinion it is fully adequate, in scope and quality, as a thesis for the degree of Master of Science.

Supervisor
Asst.Prof.Dr.Doğan Sorguç

I certify that this thesis satisfies all the requirements as a thesis for the degree of Master of Science.

Chairman of the Civil Engineering Department
Assoc.Prof.Dr.Mehmet Kıcıman

Examining Committee in Charge:

ABSTRACT

Taha Aksoy, M.S.

Middle East Technical University, 1972

The necessity of planning is analyzed from macroeconomical, juridical and rationalization viewpoints. The
function of planning in construction industry is also
discussed.

The advantages and disadvantages of various construction planning methods are discussed in general. The fundamentals and logical background of network based planning techniques are explained and exemplified, for arrow and precedence diagrams separately. These two network types are compared and some criteria for selection are stated.

The network design procedure is illustrated for the case of Yeşilköy Airfield Infrastructure Project.

The factors to be considered in all steps of network design are given.

The computational procedure for network based systems are illustrated systematically. The role of computers in network computations is described, by explaining the factors, benefits and problems of computer usage. The two available computer programs PCS and BKN are described in detail and compared in various aspects.

The role of project control in the overall planning effort is discussed and typical project control cycle is presented.

The factors which are to be paid attention for the effective planning and control of construction works are stated under the light of this study.

ÖZET

Taha Aksoy, Y.Lisans Orta Doğu Teknik Üniversitesi, 1972

Bu çalışmada, plânlamanın makro-ekonomik gerekliliği üzerinde durulmakta ve inşaat endüstrisindeki yeri ve gereği rasyonalizasyon ve hukukî açılardan açıklanmaktadır.

İnşaat sektöründe kullanılan plânlama yöntemleri genel olarak eleştirilmekte, bu sektörde kullanılması en uygun bulunan, ancak uygulamanın yabancısı olduğu ağ diagramlarına dayalı plânlama yöntemlerinin temelleri ve mantıksal yapıları örneklerle açıklanmaktadır. Diagram tiplerinin karşılaştırılması sonucunda varılan bazı kıstaslar verilmektedir.

Ağ diagramlarının hazırlanışında izlenecek yol,
Yeşilköy Havalimanı Altyapı İnşaatı örnek alınarak
açıklanmaktadır.

Ağ diagramları ile ilgili hesaplamaların yöntemi ayrıntılı ve sistematik olarak sunulmakta, ayrıca elektronik hesaplayıcıların yeri ve önemi üzerinde durulmaktadır. Mevcut kompüter programları (PCS ve BKN) çeşitli yönlerden karşılaştırılmaktadır.

Proje denetiminin, plânlama çabaları içindeki yerinin ve öneminin açıklanmasından sonra, denetim mekanizmasının işleyişini gösteren tipik bir şema verilmektedir.

Yapılan çalışmanın ışığı altında, etkili plânlama için üzerinde önemle durulması gereken faktörler açıklanmaktadır.

ACKNOWLEDGEMENTS

It is the author's pleasure to express his deepest gratitute to Dr.Doğan Sorguç, Head of the Division of Construction Engineering Studies and the Strategy of Construction in Civil Engineering Department, for his active support, creative criticism and invaluable help in the design and implementation of this research work.

The author also wishes to thank to all the members of the Directorate of the 1.District of Airfields and P.O.L. Installations Construction Department, especially to Mr.Muhterem Ortaç, the chief controlling engineer, for their constructive cooperation throughout the course of this study.

Miss Nur Özkan, who has sacrificied many precious days for typing this thesis, must be thanked.

Tx : standard deviation of expected project duration

ES : activity's earliest start time

EE : activity's earliest end time

LS : activity's latest start time

LE : activity's latest end time

CHAPTER I

INTRODUCTION

Construction sector, especially in developing countries, is of great importance from economical point of view. Because, as will be explained in Chapter II, a large portion of annual investments are allocated to this sector. In developing countries this share is even larger. It follows that the development efforts of these countries will be affected very affirmatively by the rational use of construction investments.

There are several measures to be taken to rationalize the construction sector among which construction planning has a sinificant role. The analysis and evaluation of construction planning techniques through application, constitutes the major aim of this study. For this purpose the Yeşilköy Airfield Infrastructure Project is selected for case study to analyze from planning viewpoint with cooperation of the Ministry of Public Works.

This project is a part of the Yeşilköy Airfield Extension Project which covers the following items (1):

- construction of a second runway,
- construction of a network of taxiways,
- extension of the present runway,
- construction of a new international air terminal and modernization of the present one,
- modification and/or extension of the various existing utilities.

The first two items of the extension project are, at this stage, the objectives of the infrastructure project.

This work, whose estimated cost is 84 425 923.- TL., was awarded to Fitzpatrick Overseas Itd. on June 7, 1968; to be completed within 1200 calender days after the receipt of the written order to commence work⁽²⁾. The contractor has started the work on site (Figure 1) on September 30, 1968 with an insufficient work capacity⁽³⁾, which remained so until the end of April 1969. In this month he has enlarged his earthwork fleet which became mainly composed of: 17 bulldosers, 8 motorscrapers, 3 tractors, 3 excavators, 2 loading showels, 1 backhoe and 7 compacting rollers. During the next 5 month the following were added to the equipment list: batch plant, 2 cement silos, 14 belt conveyors, 10 mobile cranes, 8 concrete mixers, 1 forklift, 1 concrete paver, 5 concrete spreading and finisihing machines, steel forms, air compressors etc.

The supervision of the project was to be carried out by the Directorate of 1. District of Airfields and P.O.L. (Petroleum, Oil and Lubrication) Installations Construction Department, which also prepared the documents for partial payments.

In the course of this study various problems related to construction planning are dealt with. The problems are analyzed in general on the example of the Yeşilköy Airfield Infrastructure Project wherever possible.

While discussing the construction planning methods in various aspects the emphasis is laid on the network based

planning methods with which the Turkish practice is not familiar yet. Therefore these new management tools are handled in detailed, with the hope that they will serve Turkish construction sector in the shortest possible time.

In the preparation of job schedules by network systems the available computer programs (PCS and BKN) are employed. A great portion of computer outputs are included in this work in spite of their large volume, for better illustration purposes, enabling a detailed analysis of the project and comparison of the computer programs.

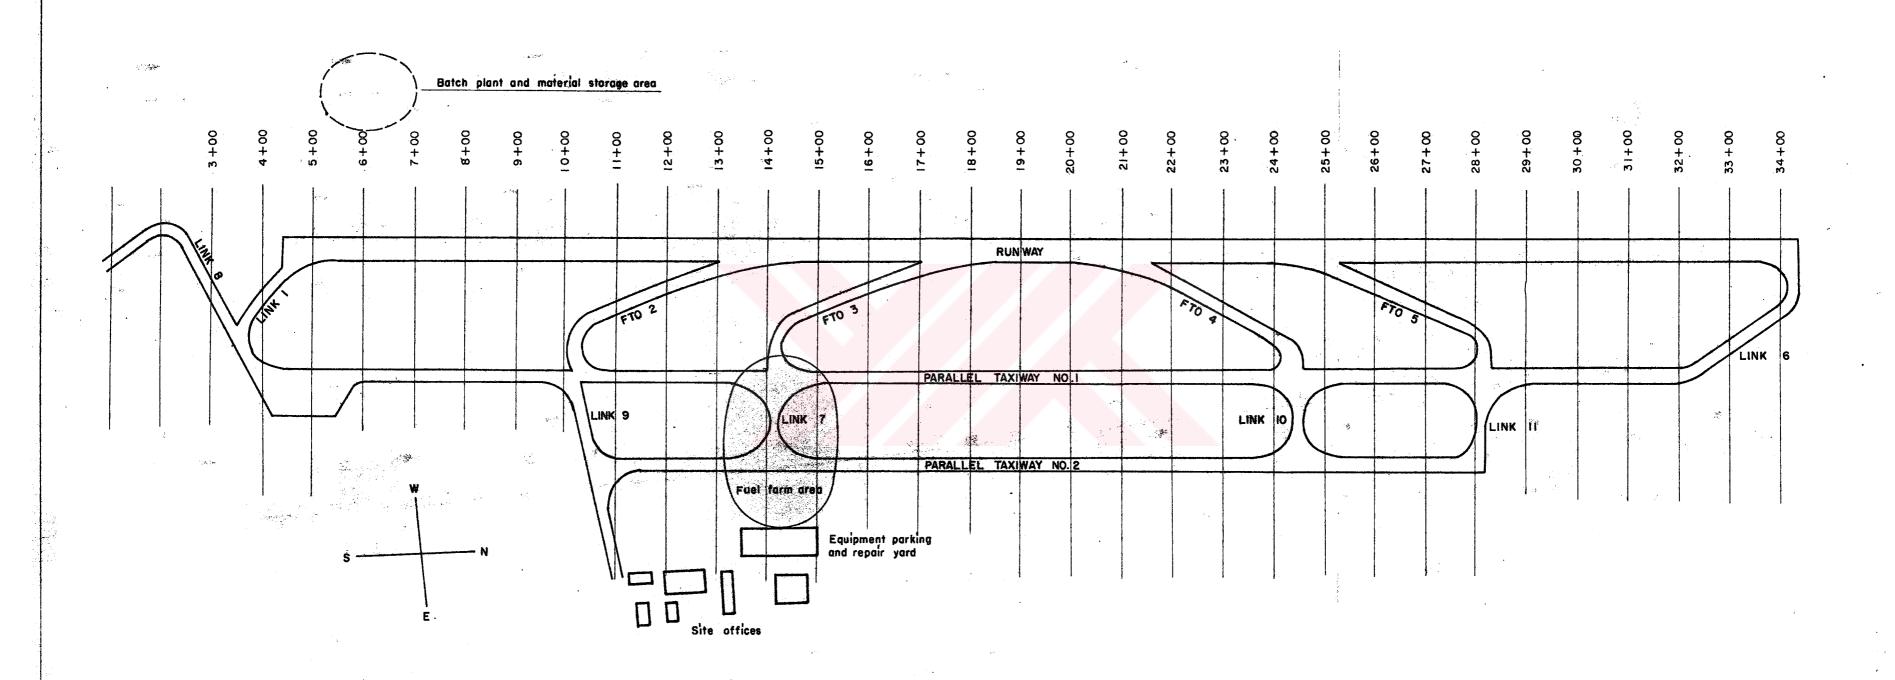

FIGURE I : YEŞİLKÖY AIRFIELD INFRASTRUCTURE CONSTRUCTION SITE LAYOUT

CHAPTER II

THE NECESSITY FOR PLANNING

A. MACRO-ECONOMICAL PLANNING

In all countries, the available resources are not sufficient to produce consuming goods and services by which the needs of citizens will be satisfied. This fact necessitates the existence of some mechanism that will make possible to decide on the needs to be satisfied and their priority in function of time and available resources. Such a mechanism, which is commonly called as "macro-economical planning", is needed more in developing countries, since the gab between the needs and the potentialities of these countries is larger than in industrialized ones.

Economical planning consists primarily of a twofold process of coordination:

- i.Coordination of objectives; this involves laying down the priorities and allocating them to the selected targets.
- ii.Coordination of resources to be employed to achieve these targets.

Coordination is necessary for both the overall development and the current running of an economy; it involves, first, analysis of interactions between the component parts of the economy and then controlling and rearranging the functioning of these parts to balance and

to synchronize the whole system. Coordination must be projected several years ahead and this necessitates forecasting the factors which will govern the production and consumption. Therefore, economic planning may be defined as (4): "high-level coordination based upon forecasts of certain basic factors in the economy".

Macro-economical planning is the only rational mean by which proper account can be taken of interactions between the various component elements of an economy. Planning, in a developing country, provides a general picture of developments in economical, technological, fiscal, social, juridical and other fields as well as the related changes in the structure of the economy.

The growth of any developing economy
can neither be directed without planning nor can be
properly controlled, since without planning there can be
no clear concept of the interplays between the factors
and mechanisms which control the operation and even more
the development of an economic system towards a selected
target. Therefore the growth of developing economies must
be guided by planning.

There exists a strong interrelationship between the terms "planning" and "development", since what is meant by development automatically becomes the objectives of planning. In the broadest sense, the main target of planning is to promote the social welfare (5). The economical way to achieve this target is to raise the living standard of citizens. If there exists an even distribution of income in a country, the standard of living can be expressed as (6):

$$L_{1} = \frac{P_{1}^{0}}{N_{i}} \tag{1}$$

where L_i - living standard in year i

Pi - total GNP in year i

N_i - population in year i

Then the annual rate of increase in living standard (L') becomes:

$$L^{\circ} = \frac{\Delta L}{L_{i}}$$

$$= \frac{L_{i+1} + L_{i}}{L_{i}}$$

$$= \frac{P_{i+1}^{\circ} - P_{i}^{\circ}}{N_{i+1} - N_{i}}$$

$$= \frac{P_{i}^{\circ}}{N_{i}}$$
(2)

Defining annual rate of increase of GNP $(P^{O'})$ and annual rate of increase of population (N°) as

$$P^{0'} = \frac{P_{i+1}^{0} - P_{i}^{0}}{P_{i}^{0}} = \frac{\triangle P^{0}}{P_{i}^{0}}$$

$$N^{0} = \frac{N_{i+1} - N_{i}}{N_{i}} = \frac{\triangle N}{N_{i}}$$

Equation (2) may be rewritten as

$$L^{\circ} = \frac{P_{\underline{i}}^{\circ}(1+P^{\circ}) \qquad P_{\underline{i}}^{\circ}}{\frac{P_{\underline{i}}^{\circ}}{N_{\underline{i}}}}$$

$$\frac{1+P^{0'}}{1+N^{0}} - 1$$

$$\frac{P0'-N^{0}}{1+N^{0}}$$
(3)

By defining avarage consumption $\overline{\mathbf{C}}_{\mathbf{N}}$ as

$$\overline{C}_{N} = \frac{V_{c} \cdot C_{V}}{N_{i}} \tag{4}$$

where V_c - total amount of consumption

e - unit cost of consuming goods

then, annual gross national product may written as follows

$$P_{\hat{1}}^{\mathbb{Q}} = N_{\hat{1}} \cdot \overline{C}_{N} + I_{\hat{s}}$$

where I_s - total annual saving

If the number of employed people is A and GNP per employed person (overall productivity) is \overline{P}_{2}^{O} then

$$A \cdot \overline{P}^{0} = N_{1} \cdot \overline{C}_{N} + I_{s}$$

Taking the annual savings approximately equal to annual investments

$$I_{i} = (AP^{0} - NC_{N})_{i}$$

where I_i - total annual investment

Defining k as the amount of investment needed for a unit increase in GNP as,

$$k_{i} = \frac{I_{i}}{\sqrt{P^{0}}}$$

Then the value of P^O becomes

$$\mathbf{P}^{\odot^{l}} = \frac{\triangle \mathbf{P}^{O}}{\mathbf{P}_{i}^{O}}$$

Replacing P° in equation (3) by this value of P°,

$$L^{\circ} = \frac{(\overline{AP^{\circ}} - \overline{NC_{N}})_{1}}{P_{1}k_{1}} - N^{\circ}$$

$$1 + N^{\circ}$$

Defining the ratio of employment (ϕ) as

$$\varphi = \frac{\mathbf{A}}{\mathbf{N_i}}$$

The rate of increase of living standard takes the following final form:

$$L' = \frac{N_{i} (\varphi \overline{P}^{o} - \overline{C}_{N}) - N'P_{i}^{o} k_{i}}{(1+N') P_{i}^{o} k_{i}}$$
(5)

As the equation (5) clearly indicates, the following subobjectives should be achieved in order to accelarate the increase of living standard:

- a. To create new economic fields of work increasing the ratio of employment (ϕ).
- b. To raise the level of overall productivity $(\overline{P}^{\mathbb{O}})$ by applying appropriate methods.
- c. To reduce avarage consumption (\overline{C}_N) by decreasing either the amount of consumption (V_c) as in directed economies or the unit cost of consuming goods (c_V) as in free market economies.

- d. To reduce the rate of increase of population (N°) by birth control.
- e. To reduce the adverse effect of k which tends to increase during the economical development by employing more advanced and rational technologies. The increasing tendency of factor k, due to the effect of succeeding investments, influencing the overall productivity adversely, can be controlled by optimisation of the investment structure of national economy.

B. FEASIBILITY ANALYSIS

In allocating the limited resources of a country to projects, a list of priority must be prepared, showing the contribution level of them to the development of the whole economy. The exact selection of economically sound projects is of extreme importance, because only by this way the overall productivity (\overline{P}^0) can be raised and also the increasing tendency of factor k can be controlled. Economical soundness of projects and their contributions to national economy can be determined by feasibility analysis. In the following paragraphs the methodology of such a feasibility study is presented on Yeşilköy Airfield Extension Project (7).

1. Objective: The economical objective of the proposed investments for the extension of Yeşilköy Airfield is to create additional capacity, thereby preventing the economical losses that will be caused by the demand for passenger and freight transportation which is expected to exceed the present capacity by 1972,

and to optimize the contribution of those investments to the national economy.

- 2. Period of Analysis: Since it was proposed that the project will be completed by 1972, this year is taken as the starting year of the period. A service life of 15 years is estimated for all project elements.
- 3. Benefits: The net revenues which are estimated to be realized due to extra capacity of passenger and freight transportation and of airport services over the existing capacity of the airfield are taken as the benefits of the project.

The computational procedure followed in the determination of revenues may be explained by the following set of relations in which 1971 worths of all revenues and expenditures are computed for comparison purposes.

$$R = \sum_{j} (R_{1j} + R_{2j} + R_{3j})$$
 $j = 1, 2, ..., n.$

where R - 1971 worth of total net revenue

 R_{lj} - 1971 worth of annual net revenue due to passenger transportation in the j^{th} year of the period

 R_{2j} 1971 worth of annual net revenue due to freight transportation in the j^{th} year of the period

 R_{3j}^{-} 1971 worth of annual net revenue due to airport services in the jth year of the period

n - number of years in the period of analysis

a. 1971 worth of annual net revenue due to passenger transportation:

$$R_{1j} = (N_{j} - N_{o}) (P_{I} - C_{I}) \frac{1}{(1+i)^{j}}$$

where N_j - number of passenger to be transported in the j^{th} year

 N_{\odot} - number of passengers transported in 1971

P_I - price of passenger transport to the avarage distance

 c_{I} - cost of passenger transport to the avarage distance

i - the current interest rate

The number of passengers to be transported are forecast for each year of the study period depending on the projections made (1) by means of available data.

 $P_{\rm I}$ (and $C_{\rm I}$) are determined separately for domestic and international lines by multiplying the weighed avarage distance of transportation by the unit price (cost) of travel.

b. 1971 worth of annual net revenue due to freight transportation:

$$R_{2j} = (L_{j} - L_{o}) (P_{II} - C_{II}) \frac{1}{(1+i)j}$$

where L_j - amount of freight to be transported in the j^{th} year

 L_{o} - amount of freight transported in 1971

 $P_{\overline{II}^-}$ unit price of freight transportation to the avarage distance

 $c_{ extsf{II}^-}$ unit cost of freight transportation to the avarage distance

c. 1971 worth of annual net revenue due to airport services:

$$R_{3j} = 0.35 (M_{j} - M_{o}) \frac{1}{(1+i)j}$$

where M_j - gross revenue of airport services in the j^{th} year

 $\rm M_{\odot}$ - gross revenue of airport services in 1971 In this formula, it is assumed that 35 percent of the gross revenue is the net revenue (7).

- 4. Investments and Expenditures
- a. Investments

According to the information obtained from the Airfields and P.O.L. Installations Construction

Department (HATIR) the investment program of Yeşilköy

Airfield Extension Project covers the investments to be made during the 1961-71 period for the following items:

- 1. Land expropriation
- ii. Infrastructure
- iii. Terminal buildings
 - iv. Installations for instrumental landing system
- v. Maintenance installations of Turkish Airlines

 The value of all investments at the end of 1971
 can be computed as follows:

$$I = \sum_{k} [I_{k}(1+i)^{m-k}] \quad k = 1, 2, ..., m$$

where I - 1971 worth of all investments

 I_k - amount of investment made in the $k^{\mbox{th}}$ year of the investment period

m - number of years in the investment period

b. Expenditures

The annual expenditures that will be made for the maintenance and the repairs of all installations, which will not increase their inventory value and will not extend their service lives, are estimated. The operational expenditures are not considered, since they were included in the computation of net revenues. Then 1971 worth of all annual expenditures is computed as:

$$E = E_1 \cdot \frac{(1+i)^n - 1}{i (1+i)^n}$$

where E = 1971 worth of all annual maintenance expenditures

E₁ - annual maintenance expenditure

5. Salvage Value

The theoretical economical lives of project elements varies between 25-50 years. But considering the fact that circumstances change very rapidly in air transportation field affecting the accuracy of demand forecasts adversely, the service lives of all project elements are taken as 15 years. The salvage values of installation are, thus, estimated for the end of this period. Then the 1971 worth of the total salvage value is computed as:

$$s = s_{15} \frac{1}{(1+1)^{15}}$$

where S - 1971 worth of salvage value

 $\rm S_{15}^{-}$ salvage value of all project elements at the end of their service life

6. Rentability

The result of a feasibility study can be expressed by the rentability value of the project. Two different formulas are being used for computing the rentability value. For instance, the State Highway Department takes the ratio of the difference between benefits and costs to costs, where the Airfields and P.O... Installations Construction Department uses the benefit—cost ratio in rentability computation. Taking the latter one, the rentability value of the project can be expressed as:

where r - rentability value

If the current interest rate is 7% the value of r

becomes 3.97 (397 %). This value is found to be 5.85

(585%) for Bursa Airfield Project (8).

C. CONSTRUCTION PLANNING

- l. Economical Basis
- a. Rationalisation

construction sector is of great importance especially in developing countries. This fact can be observed from the investment distribution within the various sectors of economy in such countries. As the table 1 shows 60.8-76.4 % of total investments have been allocated to construction sector during the years 1956-1966, in Turkey.

Table 1. Construction Investments

Year	Total Cons Investment Private	-		Construction I Investment of Public	
1956	1260.6	1191.0	37.5	35.4	72.9
1957	1417.8	1644.4	36.3	42.1	76.4
1958	1744.0	1824.6	35.6	37.2	72.8
1959	1985.4	2411.7	29.7	36.0	64.7
1960	2080.8	2736.4	27.7	36.4	64.1
1961	2107.5	2810.1	26.9	35.8	62.7
1962	2386.4	2906.3	27.4	33.4	60.8
1963	2637.7	3307.7	27.6	34.6	62.2
1964	2905.6	3807.5	29.1	38.9	68.0
1965	3438.6	4142.3	33.6	41.6	75.2
1966	4124.8	5162.7	30.1	37.6	67.7

Source: The Economic Report 1968 10)

Since construction investments have such a large share in total investments, any attempt to reduce construction costs would influence the productivity of overall investments. At the same time, if cost reduction can be realized in this field, it will directly affect the amount of avarage consumption (\overline{C}_N) , because the unit cost of consuming goods and services (c_V) will be reduced. Consequently, the rate of increase of living standard (L') will speed up in connection with the decreased value of \overline{C}_N .

The cost structure of constructions must be carefully analyzed in order to be able to determine the necessary and effective measures to be taken for cost reduction. In the following paragraphs a cost model (11) will be given which elearly illustrates the cost structure of constructions:

$$C = C_1 + C_2 + C_3 + (1 + \lambda) C_4$$

where C - total cost of construction

C1 - land cost

C₂ - interest cost

C₃ - consultation cost

 C_{Δ} - production cost

> - factor of contractor's profit

Among these cost factors, production cost (C_4) has the largest share (up to 70%). Therefore the primary objective of rationalisation in construction sector should be the reduction of production costs.

The production cost (C4) may be defined as:

$$C_4 = C_{41} + C_{42} + C_{43} + C_{44} + C_{45}$$

where C_{41} cost of moving in (ie. cost of erecting equipment and plants)

 C_{42} site overhead cost (ie. costs in site office)

 C_{43} business cost (ie. administrative costs)

 $C_{h,h}$ capacity cost (ie. cost of labor and equipment)

 C_{45} cost of construction materials

Generally in buildings, C_{45} constitutes 60% of the production cost (C_4) and the share of other factors in C_4 are:

 C_{44} , 30 %; C_{41} , C_{42} and C_{43} , althogether, 10 %.

If we analyze further, the factors having large shares (c_{44} and c_{45}):

Capacity Cost (C44)

The primary elements of capacity are labor and machinery. Therefore the capacity cost (C_{44}) depends on the quantity of laborers (A) and of machines (B), their unit costs (c_A, c_B) , their efficiencies (a, b) and their working times (h_A, h_B) . The mathematical expression of this statement is:

$$C_{44} = \frac{1}{e_1 \cdot e_2} \left[\frac{1}{a} A h_A e_A + \frac{1}{b} B h_B e_B \right]$$

where e₁ - job efficiency

e, - management efficiency

a - labor efficiency

b - efficiency of machinery

A - number of manual laborers

B - quantity of machinery (tons)

h_A - working time of laborers (hrs)

h_R - working time of machines (hrs)

© _ unit cost of labor (MU/hr /laborer)

e_R - unit cost of machinery (MU/hr/ton)

It is obvious from this formula that the measures to be taken to reduce the capacity cost $(C_{A/4})$ are mainly:

i) maximization of the job efficiency (e₁) by preparing convenient designs for speedy, easy and well defined production;

- ii) maximization of the management efficiency (e_2) by effective site planning and job scheduling considering repetitions and flow work;
- iii) maximization of the labor and machinery efficiencies
 (a, b) by training the personnel, paying wages according to
 performance and by microplanning, ie., planning and organising
 the job place in order to create favorable job conditions in
 viewpoint of higher productivity and less strain.
- iv) determination of the optimum grade of mechanisation $(d=h_R\cdot B/h_A\cdot A) \ corresponding \ to \ minimum \ capacity \ cost \ (C_4).$

Materials Cost (C45)

The materials cost (C_{45}) is a function of definite variables some of which reflects the influence of external conditions. Mathematically:

$$C_{45} = S (c_s + 1.c_T)$$

where S = quantity of materials used (tons)

c_s - unit cost of materials (MU/ton)

1 - transportation distance (Km)

 $c_{\eta \eta}$ - unit cost of transportation (MU/Km/ton)

The measures to be taken to keep the materials cost $(C_{A,5})$ low are:

- i) minimization of the amount of materials to be used by:
- increasing the ratio of useful area to construction area,
 - preparing structural designs which save material,
 - good quality control during construction,
 - -preventing the waste of material

- ii) minimization of the unit cost of materials (c_s). This factor can be affected only by macro-economical measures such as:
- encouraging the mass production methods in construction materials industry,
- allocating sufficient financial credits for industrialisation in this field,
 - standardisation of contruction materials
- creating a steady demand level (public demand) for construction materials,
- iii)minimization of the transportation distance (1) and the unit cost of transportation ($\varepsilon_{\rm T}$) by using local construction materials wherever possible.

b. The Planning Function

Planning is the process of coordinating the elements of work (activities) and production (partners) in function of time, considering flow work and resource leveling which increase productivity and decrease costs.

Therefore it involves the selection of the system of work to be adopted for a project from all the alternative ways and sequences in which it could be done.

The first step of construction planning process is the selection of the optimum capacity for the given project. In this step the optimum value of grade of mechanisation (d), qualification of workmanship and of equipment, and the local materials to be used are determined.

The second step is the sequencing of project activities. Atmost care should be experienced in sequencing

the activities to increase the productivity of both labor (a) and machinery (b) by reducing time losses due to shifting of teams from one place to another. The labor productivity (a) can also be increased by providing a team to work on similar types of work. By proper sequencing of activities the need for extra capacity can be reduced to minimum without extending the project duration. This process is known as "resource leveling" and is a very effective measure for reducing the capacity cost (C_{44}) .

In cases where the project completion date is not given, the project duration corresponding to the minimum value of project total cost should be selected. As discussed in Chapter V, total project cost includes losses due to late completion and benefits of early completion. Therefore accomplishing a project in its optimum duration increases its contribution to the national economy.

Based on the aforegoing discussion its possible to conclude that "planning is a very effective mean of rationalisation, i.e., in reducing the construction costs". The degree of effectiveness, of course, depends on many factors among which the followings may be stated: availability of reliable data, a suitable organizational structure which ensures the collection of them by information flow and acts accordingly with proper cooperation, and selection of an appropriate planning technique. These factors affect also the management efficiency.

These points will be fully discussed in the following chapters.

2. Juridical Basis

This forms the obligatory rules of action.

The general requirements for construction planning are stated in the Article 6 of the "General Provisions for Public Works" (13) which takes place among contract documents of all public biddings as:

"The contractor shall prepare a work program and shall have it approved by the administration. In this program all project days, excluding official holidays and days with unfavorable weather, will be taken as working days.

The contractor has to conform exactly with the work program approved by the administration."

On the other hand, "Annual Program - 1969" (14) which is prepared by the State Planning Organization in accordance with the "Second 5 - Year Development Plan" accepted by the Parliament, states that:

"In planning the projects having estimated costs upto 100 million TL, "bar chart" method will be used. The projects with estimated costs over 100 million TL will be planned by planning methods like CPM or PERT."

Further requirements may be included in general specifications of the related administration. For instance, the requirements of the Airfields and P.O.L. Installations Construction Department for the planning of Yeşilköy Airfield Infrastructure Project are (2);

"Within 15 days after the contractor is informed that the contract is approved, He shall submit a detailed

work program prepared separately for each work section showing also the progress of work,

This program which shall be prepared in conformity with the type given by the Administration, shall also indicate the fixed dates of the progress of the work, specially of the various installations, material stockpiling and arrival of the main materials to the job site etc.

The contractor shall inform the Administration in writing, immediately after each delay in the work program and state the reasons of delay, and the period of delay, and the measures He should take to overcome this delay.

If during construction work the Control Engineer notices any deviation from the work program and warns the Contractor, the latter must prepare and submit a new work program, within 8 days after receiving this warning. This work program must have the necessary corrections in order to prevent any delay in completing the project within the allowed duration.

With the acceptance of this new program the Contractor has to make the necessary changes in his job site organization. All additional expenses as result of these changes shall be the responsibility of the Contractor.

In cases when the accepted new program cannot meet the given project end date, the contractor will not be released from any delay penalties.

An operation plan clearly showing the progress of work on the job site shall be submitted to the Control Engineer in three copies in every 15 days. This plan shall also include a scaled graph showing the completion percentages of all kinds of construction previously asked for and the gradual progress of work on the job site."

CHAPTER III

CONSTRUCTION PLANNING METHODS

A. GANTT CHART

The Gantt Chart is a series of horizontal bars plotted against a time scale, each bar representing beginning and completion times, together with duration of a work item in a project. In addition, a second line parallel to the first one may be drawn for each project element, to show actual work done against the required one given in the original plan, indicating the performance.

The Gantt Chart, which is also known as bar chart, has found wide area of application as a planning technique in various fields of industry, since Herny Gantt invented it around 1900. The advantages offered by this technique have led managers to adopt it. These advantages may be summarized as:

The Bar Chart can be understood very quickly and completely not only by the project managers, but also by their subordinates and superiors Because:

- The organizations are used to it, since it is an old method of planning,
- It is simple, since work is presented very clearly in function of time.

But as the contemporary management began to deal with large scale and complex engineering projects some fundamental weaknesses in bar charts were observed.

These weaknesses are:

- i) The conventional bar charts do not display interdependencies between the project elements, which are general work items, each represented by a bar, and activities. Since such interdepencies should be kept in mind while preparing the bar chart, they should also be reflected in charts in order to control and discuss the plan easily. This is especially true in large-scale and complex projects involving numerous activities with various types of interrelations.
- ii) Since bar charts do not show relationships between time and volume of works, they are one-dimensional. This fact limits their performance in comparison with other methods of planning, especially with cyclogrammes.
- iii) The Gantt chart does not indicate critical activities which delay the project completion date if they cannot be completed within the assigned duration, and also those activities which have some extra time for their completion over their durations, and the amount of those extra times.
- iv) Some large-scale and unusual type of projects, including those involving natural hazards and research works, may necessitate the consideration of uncertainties in planning. Since bar charts do not reflect uncertainties, they cannot be used for the planning of such projects.

The evaluation of both advantages and disadvantages of bar charts, results in the fact that they

possess low efficiency in coordination, but high efficiency in communication. For optimization purposes, bar chart may be used as a planning technique in small construction projects which consist of a small number of activities having simple relationships between them. For larger projects bar charts are developed giving the interrelations between the bars. On the other hand the advantages of the Gantt Charts in communication, may be used by displaying the project program prepared by other improved planning methods with them, thus making the program more communicative. Such a chart is presented in Appendix F for Yeşilköy Airfield Infrastructure Project.

In spite of the conclusion reached above, many construction managers in Turkey employ this method, regardless of the size and the complexity of the project to be planned, because it is simple and requires, less effort and skill for its preparation than the other techniques do. The shortcomings of barcharts have almost never been taken account, mainly because of:

- i) The concern of contractors which is usually the quick fulfillment of Article 6 of "General Provisions for Public Works (13)", to start with their construction work as soon as possible,
- ii) The lack of data and experience of contractors in other systems due to considerable fluctuations in construction sector.
- iii) The wrong policy of awarding contracts, according to which no sufficient time is left by the owner for

detailed design and planning of work,

iv) The inefficiency of supervisory mechanism, due to the lack of adequate organization and quality, which prevents the diagnosis of the disadvantages of planning by bar charts.

B. CYCLOGRAMME

A cyclogramme is a graph displaying the project elements in relation to a common unit of work and time. It is, therefore, a two-dimensional system, originally used in railway time tables. In construction, it is commonly used for planning of highway and pipeline projects, the common unit of work, in these cases, being the length in kilometers. Cyclogrammes can also be used in building construction, the common unit being, this time, (%) of completion shown for different floor levels on a vertical axis.

All possible types of relationships between the project activities can be set while planning by cyclogrammes:

a. The start of activity J depends on the completion of activity I with an associated time delay of \mathcal{E} ($\mathcal{E} \gg 0$). For instance casting of concrete (J) requires the completion of formwork erection.

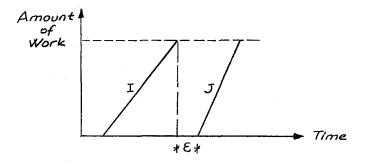

Figure 2. End to start relationship in cyclogrammes.

b. The start of activity J depends on the start of activity I with an associated time delay of \mathcal{E} ($\mathcal{E} \gg 0$). For instance excavation operation (J) can be started \mathcal{E} time units after the start of ground water lowering operation (I).

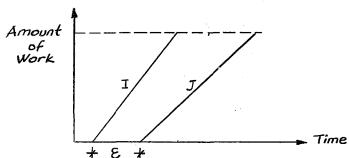

Figure 3 . Start to start relationship in cyclogrammes

c. The completion of activity J depends on the completion of activity I with an associated time delay of \mathcal{E} ($\mathcal{E} \gg O$). For instance preparation of contract documents (J) cannot be finished before completing the bills of quantities (I).

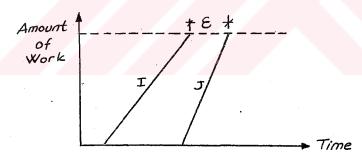

Figure 4 . End to end relationship in cyclogrammes

d. The completion of activity J depends on the start of activity I with an associated time delay of \mathcal{E} ($\mathcal{E} \gg 0$). For instance model analysis of a structure (J) can be finished if the provisional structural analysis (I) is started and a certain part of it (rough calculations) is completed.

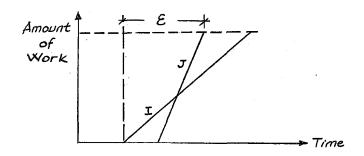

Figure 5. Start to end relationship in cyclogrammes

e. Either the start of activity J depends on the start of activity I or the completion of J depends on the completion of I with an associated time delay of ε ($\varepsilon > 0$). For instance such a relationship exists between the activities laying of pipes (J) and trench excavation (I).

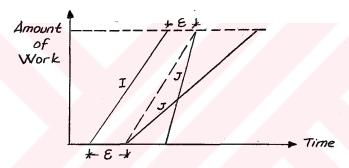

Figure 6. A combination of start to start and end to end relationship in cyclogrammes

Planning with cyclogrammes offers the following advantages.

- i) All types of relationships between the project activities can be indicated.
- ii) Each activity is plotted in such a way that its duration and volume can be easily observed.
- iii) The production rate can be determined by dividing the volume of work by the time of execution (the slope of activity line). Also, the time and place of changes in

the speed of activity execution can be seen.

Cyclogramme, as a planning technique, has some disadvantages:

- i) Its usage is restricted to the projects whose activities can be expressed in terms of a single unit of work amount.
- ii) In case of complicated or interfering flow of works, the job schedule becomes very confusing.
- iii) The critical and noncritical activities cannot be distinguished, and, therefore, the amount of extra times for noncritical activities cannot be observed in cyclogrammes.

C. NETWORK BASED PLANNING METHODS

1. Introduction

In 1956 the E.I. du Pont de Nemours Company was under a series of contracts to construct major chemical plants in America. The projects required accurate estimation of both duration and cost. The planning and controlling technique developed by this company for the above mentioned projects was originally called "project planning and scheduling" (PPS). This method improved into the "critical path method" (CPM) which represented project logic in graphic form in 1957 when Univac Application Research Section joined the program.

On the other hand, the U.S.Navy was concerned with the control of contracts for its Polaris Missile Program. These contracts included research and development work as well as the manufacture of component

parts which were never made before. Therefore neither cost nor time could be estimated accurately, as a consequence completion times had to be based on probability. Contractors were asked to estimate their time requirements on three bases: optimistic, pessimistic and most likely dates. Assuming a β distribution form these estimates were then mathematically assessed to determine the probable completion date for each project. This procedure was referred to as "program evaluation and review technique" abbreviated to PERT. This method did not consider cost as a variable but later the cost data on the same sort of probability basis has been introduced, and this system is known as PERT/COST.

Between the years 1963 and 1967 Prof.Burkhart, director of the Institute for Construction Management Science in the Technical University of Munchen has developed a new network based system and named as "Baukastennetz" (18) abbreviated to BKN, which handles only the projects having activities of definite durations. Later on, he has developed other programs to be used with the original one to handle the special aspects of planning. These are (see Appendix B.2.II): BKN-BAR, BKN-BLOCK, BKN-CUT, BKN-PERM, BKN-CONTROL, BKN-MOD, BKN-POT and BKN-COST.

Network based planning methods are new and powerful tools for planning and management of all types of projects. They involve, first the representation of a project implementation plan by a schematic diagram (network) that illustrates the sequence and interrelation of all component

parts of the project, and then the logical analysis and manipulation of this network in determining the best overall program of operation. Among these methods CPM and BKN draw special attention in construction industry, and provide a more useful and precise approach than the conventional bar charts and cyclogrammes.

2. Advantages of Network Based Methods

Network based planning techniques have found a wide area of application especially in planning and controlling of large construction projects. The reasons of their rapid adoption may be summarized as:

- i) The determination of critical path which is of prime importance in project implementation and control related with time scheduling.
- ii) The ability to show realistically and comprehensively the interdependencies between the project subelements enabling easy controls and discussion of alternatives.
- iii) The potentiality for a more realistic estimation of the total length and cost of the project because of a fine breakdown of the project into many small activities provided that reliable data are available. The need for such data forces the development of data banks.
- iv) During the execution of the project, the use of computers enable the systematic and rapid reviewing of current situations as well as evaluation of future developments so that allowance can be made at once in case of any deviation from the original plan. Short time controls increase the efficiencies of planning and management considerably.

- v) The use of computers decreases the time of planning by cancelling routine calculation work originally made by engineer. This reduces the cost of planning and control and enables the consideration of possible alternatives, thus increasing again the efficiency of planning and control.
- iv) Computer prints can be used as control documents showing deviations and responsibilities. They may also be used as contract documents in new agrements between the owner and the contractor, related with changes in the work schedule.
- vii) The program evaluation and review technique (PERT) enables the planning and controlling of research and development projects whose activities are uncertain in terms of duration and cost.

The objections raised, in spite of the advantages offered, to network based systems focus at two points:

- i) In comparison with the bar chart, the network systems are complex management tools. The bar chart is simple to prepare and its two coordinates, time and effort, are simple to visualize on the scales of the chart. But a network is basically nondimensional and does not provide scales for the measurement of time and effort.
- ii) Since the network based methods are essentially computer oriented techniques, their application costs are high for small projects.

The objection related to the problem of communication can be nullified by displaying the network analysis results by bar charts. The second one holds true if

computer is employed even for simple and small networks which can easily be analyzed manually.

3. Network Diagram

A network is a graph consisting of nodes and arrows representing activities and events.

Network diagrams are of two main types:

a. Arrow Diagrams

In an arrow diagram, each arrow represents one activity and the relation between activities is represented by the relation of one arrow to the others, covered by a mode; each node represents an event. The length of the arrow has no significance; it merely represents the passage of time in the direction of head. Each arrow of the network is identified by its tail and head events.

Figure 7. Activity notation in arrow diagrams

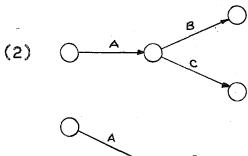

The simple logic behind this type of diagramming is that the start of all activities leaving a node, depends on the completion of all activities entering that node. This logical background is exemplified in figure 8. As the diagrams of figure 8 imply, only "end to start"type of relation can be set in an arrow diagram.

Diagram

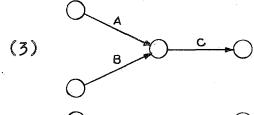

Logic

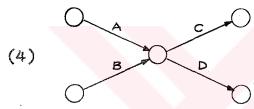

- Activity B can begin only after operation A is completed.

- Neither activity B nor C can start before activity A is completed, but B and C can be performed concurrently.

- Activity C can begin only after both activities A and B are completed.

- Neither activity C nor D can begin until both A and B are completed, but C can be started independent of D or vice-versa.

Figure 8. Elementary network logic in arrow diagrams

In some cases, dummy and artificial activities are necessarily used:

i) Dummy activities are employed to keep the logical sequencing of activities, and their interrelationship, correct. Such a case is illustrated in figure 9. If the start of activity C depends on the completion of activity A, and the start of activity D depends on the completions of activities A and B where B and C are independent activities which can be performed concurrently, the employment of dummy activity E is unavoidable to keep the logical structure of the network correct.

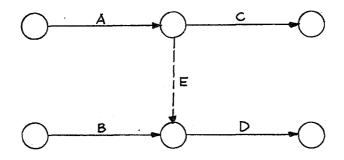

Figure 9. Use of dummy activity in arrow diagrams

ii) Dummy activities are also employed to keep the numeric designation unique, for event numbers at the tail and head of each arrow.

For example, if the starts of activities B, C and D depend on the completion of activity A and if their completions are required for the start of activity E, the use of two dummy activities is necessary, in order to be able to express activities B, C and D with different tail—head event number combunations. This case is illustrated in figure 10. a and b.

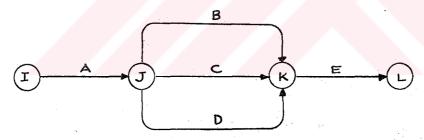

Figure 8. (a) Wrong diagramming. Because activity notation (J-K) represents B, C and D.

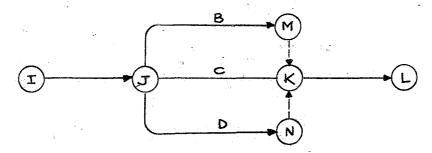

Figure 8. (b) Correct diagramming. Fach activity has different numeric designation.

The use of artificial activities may be exemplified by such a case in which time lag & is required between the completion of one activity and the start of another.

Figure 11. Use of an artificial activity $(A_{i}k)$

It is very difficult, if not impossible, to set "start to start" and "end to end" relation types between the project activities when such relationships exist. The employment of dummy and artificial activities, and breaking down some activities into pieces may assist to a certain extend in introducing such relationships into network diagrams. But resulting network does not reflect the exact logic of "start to start" and "end to end" relationships.

on the start of activity A, it is commonly attempted to display this relationship by using a dummy from head event of A to that of B, as shown in figure 12 (a). But such a diagram portion, which is equivalent to the one in figure 12 (b), shows nothing but the independency of activities A and B. Therefore it can be concluded that "start to start" relation with no time lag cannot be set in arrow diagramming.

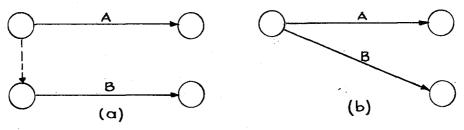

Figure 12. An attempt to set "start to start" relation.

If activity B can start $\mathcal E$ time units after the start of activity A, the breakdown of activity A into two pieces, so that first part will have duration of $\mathcal E$ and the second one (Figure 13) will have $(\mathbf t_A - \mathcal E)$ as its duration, may help in diagramming. But if A is a continuous activity which cannot be performed piecewise, the continuity between its component parts must be provided while scheduling.

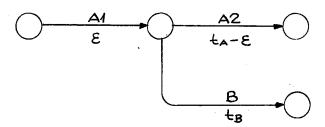

Figure 13. Partitioning of activity A to set "start to start" relation.

Another incorrect attempt is to use dummies when "end to end" relation exists between two activities (Figure 14).

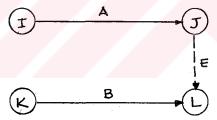

Figure 14. Incorrect use of dummy to set "end to end" relation.

The dummy activity E relates the start of activities leaving the node L to the completion of activity A. No relationship between activities A and B, other than their independency, can be observed from such diagramming. Therefore displaying "end to end" relations having no time lag is not possible.

If there exists a time lag $\mathcal E$ from completion of A to the completion of B, it is useful to break activity B down into two pieces, first having a duration of $(\mathbf t_B - \mathcal E)$ and the second having that of $\mathcal E$, to include the effect of existing relation into network computations. Again, if B is not an intermittent activity, the contunity of execution between its component parts must be provided.

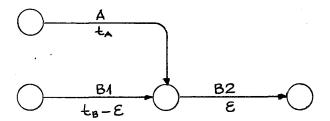

Figure 15. Partitioning of activity B to set "end to end" relation .

b. Precedence Diagrams

In a precedence diagram project activities are represented by nodes, and arrows are employed to show the relations between activities and sequence of work. Activities in a precedence diagram are identified by node codes.

Figure 16. Activity notation in precedence diagrams.

Three types of relation can be set and displayed in precedence diagrams (Figure 17).

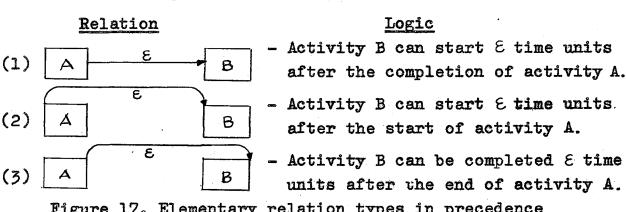

Figure 17. Elementary relation types in precedence diagrams

4. Comparison of Network Types

The logic behind precedence diagramming is that each activity has those activities as its predecessors from which there comes an arrow to it, and those activities as its successors to which an arrow goes from its representing node. The arrows also show the relevant type of relation with the amount of related minimum lag value, if any. Therefore dummy activities are not needed any more, to keep the logical sequencing of activities correct. Since, activities are represented by nodes, each having its own code, there is no need to use dummies in order to keep the labeling of activities unique. This characteristic, also eliminates the need for the special technique in coding events to ensure that head events of activities have greater numbers than their tail events.

Since all relation types can easily be set in precedence diagramming, the need for breaking up some activities into pieces, merely for network construction purposes, is eliminated. Theoretically, there is nothing wrong with breaking an activity down into several parts as is required by arrow diagramming technique. But this causes confusion, especially, at field level. Because the foreman may recognize each part as a separate activity, although they altogether form a single activity. In addition some difficulties are likely to arise in preparing cost data and in reporting system. Precedence diagramming technique compares favorably from this viewpoint.

On the other hand, employment of dummies and artificial activities, and breaking some activities down

into pieces, increase the number of activities in the network causing difficulties in its analysis. In an extreme case, the number of activities may exceed the maximum size that can be handled by the available computer programs.

In some computer programs (e.g. PCS of IBM/360) only precedence diagrams are processed. If the input data of an arrow diagram is entered, it is converted automatically into equivalent precedence network before starting with computations which consumes extra time, in turn extra cost. Therefore if such a computer program is to be used, precedence diagramming should be preferred.

The advantages of precedence diagrams over arrow diagrams can be summarized as:

- i) Elimination of dummy and artificial activities
- ii) Elimination of the necessity for breaking down some activities into pieces, thereby decreasing the number of activities in the network.
- iii) Ease and rapidity with which the planner designs the network and the field personnel grasp the concept.
- iv) Elimination of the necessity for conversion of event occurence times to activity times.

The use of arrow diagramming system may become advantageous under certain conditions. If the planner once decided not to use a computerized system, considering the factors to be discussed later on, the arrow diagramming technique has more chance in selection. Manual computation of networks becomes easier, faster and more accurate due to normal relationships between the activities. If durations

and costs of activities are uncertain, dealing with these uncertainties is extremely difficult in precedence diagrams.

In arrow diagrams, it is quite easy to observe which events and then which activities are critical. Since thre exist direct links between events, tracing the critical path is a simple operation. But in precedence diagrams, the critical activities are determined usually through a computer run and because of eliminated events, tracing the critical path may become difficult.

The nature of a project, especially if it is large size one, may necessitate the preparation of different networks, by various organizations independently. The most realistic integration of these separate networks is possible through the use of interface events, placed between them. Precedence diagrams compare unfavorably in this respect, due to elimination of events.

Therefore compared to precedence diagrams, arrow diagrams have the following advantages:

- i) Suitability for manual computations.
- ii) Ease in tracing the critical path.
- iii) Ability to employ interface events to integrate separate networks, thereby defining the transfer of responsibility from one organization to another more definitely.
- iv) Suitability for the analysis of probabilistic projects due to presence of events.

- 5. Criteria for Selecting the Network Type

 At this stage, it may be concluded that two points
 should be analyzed before deciding on the network type are:
 - i) Project characteristics (size and complexity).
 - ii) Availability of a computerized system (programmes).

It is obvious that as the number of activities to be coordinated in a project gets bigger, the need for a computerized system will increase. If such system is available, precedence diagrams, which are easy to prepare, become preferrable. Otherwise arrow diagramming has more chance to be selected, because it is more suitable for manual computations.

Complexity of a project is another criterion. In general the number of relationships as compared with number of activities and their types determine the project complexity. Since relation types which necessitate breakdown of some operations into parts in arrow diagramming technique, can be easily shown in precedence diagrams, complex projects may necessitate the employment of precedence diagrams.

Availability of a computerized system favors the preferability of precedence diagrams, since they are easy to prepare and difficult to analyze manually.

6. Physical Layout of Network Diagrams:

There are mainly three ways of displaying a network diagram:

a. Free Networks - In free networks nodes are placed on the network where space is more convenient. This type is

preferred in designing the preliminary network, because it enables the planner to concentrate his attention on dependency relations.

- b. Banded Network In banded network activities relating the same organization, function or of same type are laid out on horizontal bands. Banded networks provides easy and rapid recognition of work flow and responsibility distribution.
- c. Time-Grid Networks In time-grid networks, arrows representing the project activities are drawn horizontally, their lengths indicating the activity durations and available total float times. Non-horizontal arrows do not show any elapsed time, they merely indicate activity sequencing.

The advantages of bar charts may also be enjoyed if time-grid diagrams are put into banded form.

On the other hand, there exists another type of time-grid network showing the flow line of works in the horizontal bands and the connection of activities in vertical direction.

CHAPTER IV

NETWORK DESIGN

A. GENERAL

There are two basic ways to build up a network: forward and backward network construction. In the first one the planner selects a specific event marking the start of the project and proceeds forward establishing events and activities in chronological sequence until the terminal event marking the completion of the project reached. This method of network design is well suited to construction projects. In the second way of network design, the planner establishes the last activity at the first step, and proceeds backwards through the network, adding activities which must be completed before the object event can occur. This way is generally preferred in network design of research and development projects, since the planner often merely knows what the objective is.

In designing the network model of Yeşilköy Airfield Infrastructure Project the first way is followed. But, to enjoy the advantages of second one, forward construction technique is somewhat modified by answering the question: "what activities must be completed immediately before commencement of this activity?", in addition to the question: "what activities must be started immediately after completion of this activity?" which is to be answered necessarily in forward network construction method. Another reason of following such a modified method, is to simplify the data

preparation for computarized systems PCS and BKN, both of which ask for the specification of preceding activities of the activity under consideration.

In this chapter, the procedure for network design is analyzed through four steps: project breakdown, sequencing of activities, determination of activity durations and coding the activities. Although the Yeşilköy Airfield Infrastructure Project is taken as the base of analysis; these are the four basic steps to be followed for designing a network model of any project.

In Appendix E the final form of the network diagram is given in a banded form. The details of improvements obtaining the final form are not discussed, since they have caused considerable changes in all steps of network design.

The network diagram submitted is a precedence diagram. Although the network may not be considered as a complex one precedence diagramming is preferred, since there was computer available free of charge offering a chance to make use of it, thereby to analyze its function in planning. Another factor making this selection favorable is the number of activities which exceeds 300.

B. PROJECT BREAKDOWN

After the general task of the project is clearly recognized, breaking it down into separate operations or processes necessary for its completion, is the first step towards effective planning, in all planning techniques.

The degree of breakdown is strongly effected by the nature of the selected method. If bar charts or cyclogrammes are selected for planning purposes, the number of activities resulting from project breakdown should be kept as low as possible. But network based systems enable the planner to deal with numerous activities, thus increasing the accuracy of plans.

At this stage, it is useful to point out that network plans, presenting the work process by which the project objectives and requirements will be handled, should be prepared by those who will be responsible for supervising the work by the effective cooperation of those who carry the direct responsibility for doing the work. If this fact is overlooked, the resulting plan is likely to be unrealistic. In case of the planning of Yeşilköy Airfield Infrastructure Project the author's attempts to secure the cooperation of contracting firm did not yield the desired results, merely because of the fact that its managers had no faith in planning, some information which would possibly make this study more accurate could not be obtained. Thus, for instance, material deliveries could not be included in project breakdown due to lack of information, in spite of their importance.

The factors to be considered while breaking down a project into its component activities are given below. The order of the factors is the sequence followed in the breakdown procedure of Yeşilköy Airfield Infrastructure Project, and has no relation with the order of their importance.

Factor 1. The costing data required by the management

It is preferable to have activities for which the necessary cost figures can be computed easily. Since the necessary information could not be obtained from the contractor this factor did not have a strong effect.

Factor 2. The itimized bill of quantities

It is found very useful to break the project down into such activities that each activity will have its own unit price in the itemized bill of quantities. But an attempt to satisfy this requirement fully, may result in a very detailed breakdown making the plan impracticable.

Factor 3. The distribution of responsibility within the organization

Project activities should not, preferably, fall into responsibility area of more than one division of the organization. In this study, only the controlling organization is considered, however the responsibility structure of the contracting firm is very similar to that of controlling organization.

By the consideration of the factors 1, 2 and 3, the following general breakdown is reached for this project:

- a. Earth Work
- b. Lean Concreting
- c. Pavement Quality Concreting
- d. Shoulder Stabilization
- e. Forming Asphaltic Concrete Layer on Shoulders
- f. Constructing Drainage Structures
- g. Laying PVC Cable Pipes under Shoulders
- i. Top Soiling

In the projects requiring the execution of same type of activities over a large area, such as airport, highway and pipeline construction projects, the location of the work on the site becomes a significant factor in breakdown process. The planner can make activity descriptions readily understandable for anyone involved in the execution of the project, by referring to the locations of activities. It is found out that the breakdown of general work items in accordance with their locations is not likely to yield desired results, unless the following requirements are met:

- All general work items should be subject to the same locational breakdown, if possible;
- The breakdown should result in clearly defined and continuous activities.

In the arrow diagram, prepared and submitted by the contractor the site was divided into four zones, namely A, B, C and D, as shown in figure 18, and the locations of

activities were indicated by the symbol of the zone in which they are going to take place.

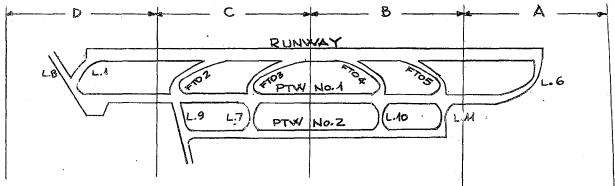

Figure 18. Original locational breakdown

Such a broad locational grouping is, of course, very advantageous in satisfying the first requirement. But a finer breakdown is needed for the satisfaction of the second one. Because any reference to one of the four zones was found to be insufficient to make the activity description clear enough. In addition, since it cannot be expected that it will be economical to complete on activity within the zone in which it is started, without any interruption, all activities will become intermittent, causing difficulties in scheduling and resource leveling. Therefore this locational breakdown has come out to be impracticable in a very short time.

After these shortcomings were observed, the contractor tried another approach to locational breakdown. In this approach, the areas to be paved were taken as bases of breakdown. The general work items were divided into parts according to their place of execution with reference to runway, taxiways, fast turn-offs and links. But even this breakdown did not yield the expected practicability.

An analysis of items of general breakdown will show that items 1 and 9 are to be performed over the whole site, where items 2 and 3 only on pavements, and items 4, 5, 6, 7 and 8 on the shoulders. This rough breakdown can make only the descriptions of component activities of items 1 and 9 clear enough. A finer breakdown is still necessary for the other items. For example, physical constraints prevents the contractor to lay pavement quality concrete on the same fast turn-off or link without interruption, so these activities will remain intermittent. On the other hand shoulder activities should be performed at least in two steps, in order to maintain work flow.

Taking the above discussion into consideration the following locational breakdowns are obtained for general work items:

a. Earth Work

Since a small amount of earth work was left when this study was started, this item is subjected to a rough breakdown. First, the remaining earth work is divided into two parts according to the nature of work to be done; then each part is divided into its component activities considering the location of the work on the site.

i) Earth Moving

- 1. On the Area to Paved in North and East
- 2. Outside the Area to be Paved in North and East
- 3. On the Fuel Farm Area.

- ii) Borrowing and Filling the Selected Material
 - 1. Outside the Fuel Farm Area
 - 2. On the Fuel Farm Area
 - b. Lean Concrete (LC)

The amount of work left at the starting date of this study was suitable for a rough breakdown:

- 1. From Parallel Taxiway No.1 (24+60) to the End of Link No.6
- 2. Parallel Taxiway No.2 (Fuel Farm Area)
- 3. Link No.10
- 4. Link No.11
- 5. Fast Turn-off No.4
- 6. Fast Turn-off No.5
- 7. Parallel Taxiway No.1 (Fuel Farm Area)
- 8. Link No.7 (Fuel Farm Area)
- c. Pavement Quality Concrete (PQC)

The nature of work in this item has necessitated a detailed locational breakdown. It has been tried to obtain such a breakdown that the resulting activities will be clearly defined and continious, and they will permit any sort of sequencing. This aim is achieved by dividing each pavement element into its strips. In addition, the strips of runway and taxiways are divided into parts, in order to be able to set their relations to shoulder activities correctly.

The locational breakdown of PQC item is:

- 1. Runway Strip No.6 (04+36 19+50)
- 2. Runway Strip No.6 (19+50 34+36)
- 3. Link No.1 South-West Strip

- 4. (Zone 1) Link No.1
- 5. (Zone 1) Runway
- 6. (Zone 1) Fast Turn-off No.2
- 7. (Zone 2) Fast Turn-off No.2
- 8. (Zone 2) Runway
- 9. (Zone 2) Fast Turn-off No.3
- 10. (Zone 3) Fast Turn-off No.3
- ll. (Zone 3) Runway
- 12. (Zone 3) Fast Turn-off No.4
- 13. (Zone 3) Parallel Taxiway No.1
- 14. (Zone 4) Fast Turn-off No.4
- 15. (Zone 4) Runway
- 16. (Zone 4) Fast Turn-off No.5
- 17. (Zone 4) Parallel Taxiway No.1
- 16. (Zone 4) Fast Turn-off No.5
- 17. (Zone 4) Parallel Taxiway No.1
- 18. (Zone 5) Fast Turn-off No.5
- 19. (Zone 5) Runway
- 20. (Zone 5) Link No.6
- 21. (Zone 5) Parallel Tawiway No.1
- 22. (Zone 6) Link No.7 (Fuel Farm Area)
- 23. (Zone 6) Parallel Taxiway No.2
- 24. (Zone 7) Link No.7 (Fuel Farm Area)
- 25. (Zone 7) Parallel Taxiway No.1
- 26. (Zone 7) Link No.10
- 27. (Zone 7) Parallel Taxiway No.2
- 28. (Zone 8) Link No.10
- 29. (Zone 8) Parallel Taxiway No.1
- 30. (Zone 8) Link No.ll

- 31. (Zone 8) Parallel Taxiway No.2
- 32. Link No.11 North Strip
- 33. Parallel Taxiway No.l East Strip (Between Links No.ll and 6)
- 34. Link No.6 North East Strip
- 35. Parallel Taxiway No.2 East Strip (Zone 6)
- 36. Parallel Taxiway No.2 East Strip (Zone 7)
- 37. Parallel Taxiway No.2 East Strip (Zone 8)
- 38. Fast Turn-off No.2 Interior Strip
- 39. Fast Turn-off No.3 Interior Strip
- 40. Fast Turn-off No.4 Interior Strip
- 41. Fast Turn-off No.5 Interior Strip
- 42. Link No.7 Interior Strip (Fuel Farm Area)
- 43. Link No.10 Interior Strip
- 44. Link No.11 Interior Strip
- 45. Parallel Taxiway No.1 Interior Strip (Zone 3)
- 46. Parallel Taxiway No.l Interior Strip (Zone 4)
- 47. Parallel Taxiway No.1 Interior Strip (Zone 5)
- 48. Parallel Taxiway No.2 Interior Strip (Zone 6)
- 49. Parallel Taxiway No.2 Interior Strip (Zone 7)
- 50. Parallel Taxiway No.2 Interior Strip (Zone 8)
- 51. Parallel Taxiway No.1 West Strip (Fuel Farm Area)
- 52. Parallel Taxiway No.1 East Strip (Fuel Farm Area)
- 53. Parallel Taxiway No.l Interior Strip (Fuel Farm Area)
- 54. Parallel Taxiway No.2 West Strip (Fuel Farm Area)
- 55. Parallel Taxiway No.2 East Strip (Fuel Farm Area)
- 56. Parallel Taxiway No.2 Interior Strip (Fuel Farm Area)
- 57. Runway Strip No.3 (34+36 04+36)
- 58. Link No.6 Interior Strip

- 59. Runway Strip No.2 (04+36 13+00)
- 60. Runway Strip No.2 (13+00 25+30)
- 61. Runway Strip No.2 (25+30 34+36)
- 62. Runway Strip No.5
- 63. Runway Strip No.4

Shoulder Activities:

- d. Shoulder Stabilization
- e. Forming Asphaltic Concrete on Shoulders
- f. Constructing Drainage Structures
- g. Laying PVC Cable Pipes under Shoulders
- h. Laying Multi-cell Cable Passes Under Shoulders

As pointed out before all of the above general work items are going to take place on shoulders. Therefore all of them are subjected to same locational breakdown in such a way that the resulting activities are well defined and continuous and their relations to PQC activities can be set easily and precisely.

Since some of the drainage activities were already completed they do not appear on activity list given in Appendix A.

- 1. Runway West Side (04+36 19+50)
- 2. Runway West Side (19+50 34+36)
- 3. Link No.8 Both Sides
- 4. Link No.1 South-West Side
- 5. (Zone 1) Link No.1
- 6. (Zone 1) Runway
- 7. (Zone 1) Fast Turn-off No.2
- 8. (Zone 1) Parallel Taxiway No.1
- 9. (Zone 2) Fast Turn-off No.2
- 10. (Zone 2) Runway

- ll. (Zone 2) Fast Turn-off No.3
- 12. (Zone 2) Parallel Taxiway No.1
- 13. (Zone 3) Fast Turn-off No.3
- 14. (Zone 3) Runway
- 15. (Zone 3) Fast Turn-off No.4
- 16. (Zone 3) Parallel Taxiway No.1
- 17. (Zone 4) Fast Turn-off No.4
- 18. (Zone 4) Runway
- 19. (Zone 4) Fast Turn-off No.5
- 20. (Zone 4) Parallel Taxiway No.1
- 21. (Zone 5) Fast Turn-off No.5
- 22. (Zone 5) Runway
- 23. (Zone 5) Link No.6
- 24. (Zone 5) Parallel Taxiway No.11
- 25. Parallel Taxiway No.l East Side and Link No.9
 South Side
- 26. (Zone 6) Link No.9
- 27. (Zone 6) Parallel Taxiway No.1
- 28. (Zone 6) Link No.7 (Fuel Farm Area)
- 29. (Zone 6) Parallel Taxiway No.2
- 30. (Zone 7) Link No.7 (Fuel Farm Area)
- 31. (Zone 7) Parallel Taxiway No.1
- 32. (Zone 7) Link No.10
- 33. (Zone 7) Parallel Taxiway No.2
- 34. (Zone 8) Link No.10
- 35. (Zone 8) Parallel Taxiway No.1
- 36. (Zone 8) Link No.11
- 37. (Zone 8) Parallel Taxiway No.2

- 38. Link No.ll North Side
- 39. Parallel Taxiway No.l East Side (Between Links No.ll and 6)
- 40. Link No.6 North and North-East Sides
- 41. Parallel Taxiway No.2 East (10+80 Fuel Farm Area)
- 42. Parallel Taxiway No.2 East (Fuel Farm Area)
- 43. Parallel Taxiway No.2 East (Fuel Farm Area-28+23)
- i. Top Soiling

The nature of this work item permits rather a rough breakdown, without causing any difficulty in satisfying the condition requiring the resulting activities to be well defined and continuous.

- 1. Runway West Side (04+36 19+50)
- 2. Runway West Side (19+50 34+36)
- 3. Area Between Links No.1 and No.8
- 4. Link No.8 South-East Side
- 5. Parallel Taxiway No.1 East-Side and Link No.9 South Side
- 6. Parallel Taxiway No.2 East Side and Link No.11
 North Side
- 7. Parallel Taxiway No.1 East Side and Link No.6
 North-East Side
- 8. Zone 1
- 9. Zone 2
- 10. Zone 3
- 11. Zone 4

- 12. Zone 5
- 13. Zone 6
- 14. Zone 7
- 15. Zone 8

The presence of the fuel farm area (figure 1) has caused an increase in the number of project activities through the project breakdown process. Its effect will be felt more strongly and adversely in formulating the construction logic, and also in the attempts to sustain an effective work flow.

C. SEQUENCING OF ACTIVITIES

After the list of project activities has been prepared (Appendix A) the next step is to set the relationships between these activities. The planner can set two types of relationship between project activities: causal and operational. Causal relationships are set due to physical constraints. Any relationship of this nature cannot be subject to change through network refinement process, if they are set correctly unless some technical invention is introduced into practice. However the planner should consider only the existing level of technology in order to be realistic. The second type of relationships are set under the consideration of operational constraints which are namely: safety, resource, finarce and management (including team work) constraints. The interrelations between the project activities, which are due to operational constraints may be subject to change when an effective change occurs in the existing conditions.

The relationships between the general work items of Yeşilköy Airfield Infrastructure Project due to physical constraints are set as follows:

a. Earth Work

- i) Earth Moving There exist no physical limitation preventing the start of the remaining earth moving operation. Consequently these activities are to be preceded by a dummy activity "Project Start".
- ii) Borrowing and Filling the Selected Material Activities of this item cannot be started with unless their
 corresponding "Earth Moving" activities are finished.
- b. Lean Concrete The start of LC activities depends on the completion of the corresponding portion of "Borrowing and Filling the Selected Material" activities. But some LC activities can immediately start since their predecessors have been already completed.
- c. Pavement Quality Concrete In general for the start of PQC activities, completion of LC activities on the location concerned is required with a time lag of at least 7 days which is necessary for lean concrete to gain its strength. PQC activities, on the locations satisfying this requirement, can start.

Once one strip of pavement quality concrete is laid, minimum waiting time of 5 days is required to lay concrete on the adjacent strip. Since all pavement elements, except runway, are composed of three strips, there are three alternative ways to be followed to complete an element:

Alternatives

Order of Execution	I	estes office	TIT
1.	Side strip	Interior strip	Side strip
2 .	Interior strip	Side strip	Side strip
3	Side strip	Side strip	Interior strip

Although selection of the alternative way to be followed is entirely free of physical constraints, this decision has to be made at this stage. Because each of these alternatives necessitates different physical relations to be set, as shown in figure 19, and no single diagrammatic representation can enable the planner to make this decision later.

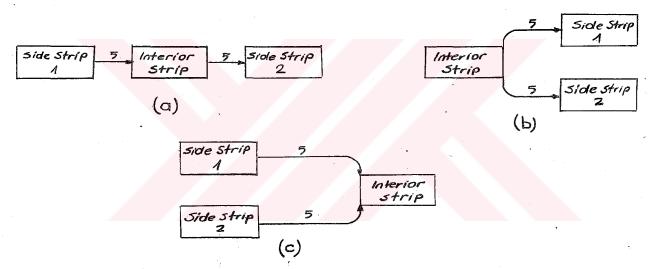

Figure 19. Alternative ways to lay PQC on pavement elements other than runway.

It is found more preferrable to suggest the third alternative which gives priority to side strips, thereby preventing probable delays in starting with shoulder activities or interruptions in their flow. This selection implies that the both edges of each side strip will require steel forms, then interior strip will be laid without form. Since the amount of steel forms available is found to be sufficient, the shortage

of steel forms is not likely to occur. Another problem may be accumulation of water between two side strips. This problem will be solved in sequencing the activities, under the consideration of operational constraints, by completing the interior strips of pavement elements whose side strips are already finished, before the rain season.

- d. Shoulder Stabilization It is obvious that shoulder stabilization activities can take place only after the completion of required installations under shoulders. These installations are PVC pipes, multi-cell cable passes and drainage pipes. Since PVC pipes may be damaged during the compaction operations, they will be planned to be laid after shoulder stabilization. On the other hand the side strip of the adjacent pavement element should be finished leaving a sufficient amount of time lag for PQC to gain its strength and for the removal of steel forms. Therefore laying down the multi-cell cable passes and drainage pipes, and concreting the side strip of the adjacent pavement element are required to precede shoulder stabilization activities. But only "multi-cell cable passes" activities are shown as preceding work items in the network. Because the start of "multi-cell cable passes" activities are related to the completion of relevant PQC and drainage activities.
- e. Forming Asphaltic Concrete on Shoulders An asphaltic concrete layer is required to be formed on stabilized shoulders. Since PVC pipes are planned to be placed after shoulder stabilization, the relation set requiring PVC pipes to be placed before forming asphaltic

concrete layer on shoulders, also indicates that shoulder stabilization activities will be completed before the start of asphaltic concrete activities.

- f. Constructing Drainage Structures Although the completion of earth work on the related location constitutes a physical constraint for the start of drainage activities, accepting the lean concreting of the adjacent pavement element as the predecessor of drainage activities is more realistic; because such an application will give better results from alignment viewpoint.
- g. Laying PVC pipes under Shoulders In order to prevent any probable damage, PVC pipes are planned to be placed after shoulder stabilization.
- h. Laying Multi-cell Cable Passes under ShouldersThis group of activities are to be preceded by PQC of the
 side strip of the adjacent pavement element with a minimum
 time lag of 8 days which is necessary for setting of concrete
 and removal of steel forms. Also the related drainage activities
 are taken as predecessors in order to prevent multi-cell cable
 passes functioning as drainage pipes.
- i. Top Soiling The activities of this item are to be executed over the whole site, excluding pavements and shoulders, and has a finishing nature. Therefore drainage activities must be finished on the related location before top soiling starts, because drainage pipes are going to remain under the top soil.

The final stage of top soiling will be smooting the top soiled area. For this reason, asphaltic concrete layers should be finished on the adjacent shoulders for better

leveling of top soiled area.

In sequencing the activities under the consideration of operational constraints the emphasis is laid on the management constraint which requires the maintenance of an effective and uninterrupted work flow within each general work item. It is expected that limitations imposed by resource and team constraints will not be exceeded if a single flow line can be established for each general work item. In this project, it is not expected that any problem will arise due to safety constraints. The problems which are likely to occur due to finance constraints are tried to be minimized by setting rather a smooth rate of execution and resource leveling.

At this level of sequencing the following points are raid atmost attention:

- Priority is given to those activities whose predecessors were already completed at the beginning of the planning process,
- Time necessary for shifting of some equipment is tried to be minimized.
- Same flow patterns are proposed for concreting and shoulder activities, wherever possible.

The presence of installations on fuel farm area whose removal time is uncertain, affected the effectiveness and continuity of any alternative work flow, adversly. Therefore the activities which are going to take place on this area are shifted towards the end of project.

The flow lines exhibited here (figure 20, 21 and 22) are the results of several trials. The procedure to obtain the given patterns is as follows:

- 1) The flow line for PQC item is established as key line, giving the emphasis on side strips which will be preceding activities of shoulder activities. The PQC activities whose predecessors are already completed are given the priority, and much effort has to be spent to minimize the adverse effect of completed portions. Some internal strips are included in this sequence list, in order to prevent equipment transfers.
- ii) The flow line for LC item is set, paying attention not to cause any interruption in PQC flow. When interriptions could not be prevented by re-sequencing of LC activities, the flow line of PQC item is revised.
- iii) The order of execution of "Earth Work" item is determined. Since the amount of work left was small in comparison with total amount, only simple arrangements are done not to disturb flow of LC activities.
- iv) The work flow lines of shoulder activities are established such that they follow the same path of execution as PQC side strip activities do. When any interruption occurs in the flow of either PQC or shoulder activities, either one or both flow lines are revised and new flow patterns are checked whether any disturbance of other flow lines is caused.
- w) The sequence of "Top Soiling" activities are determined according to order of their predecessors completions.

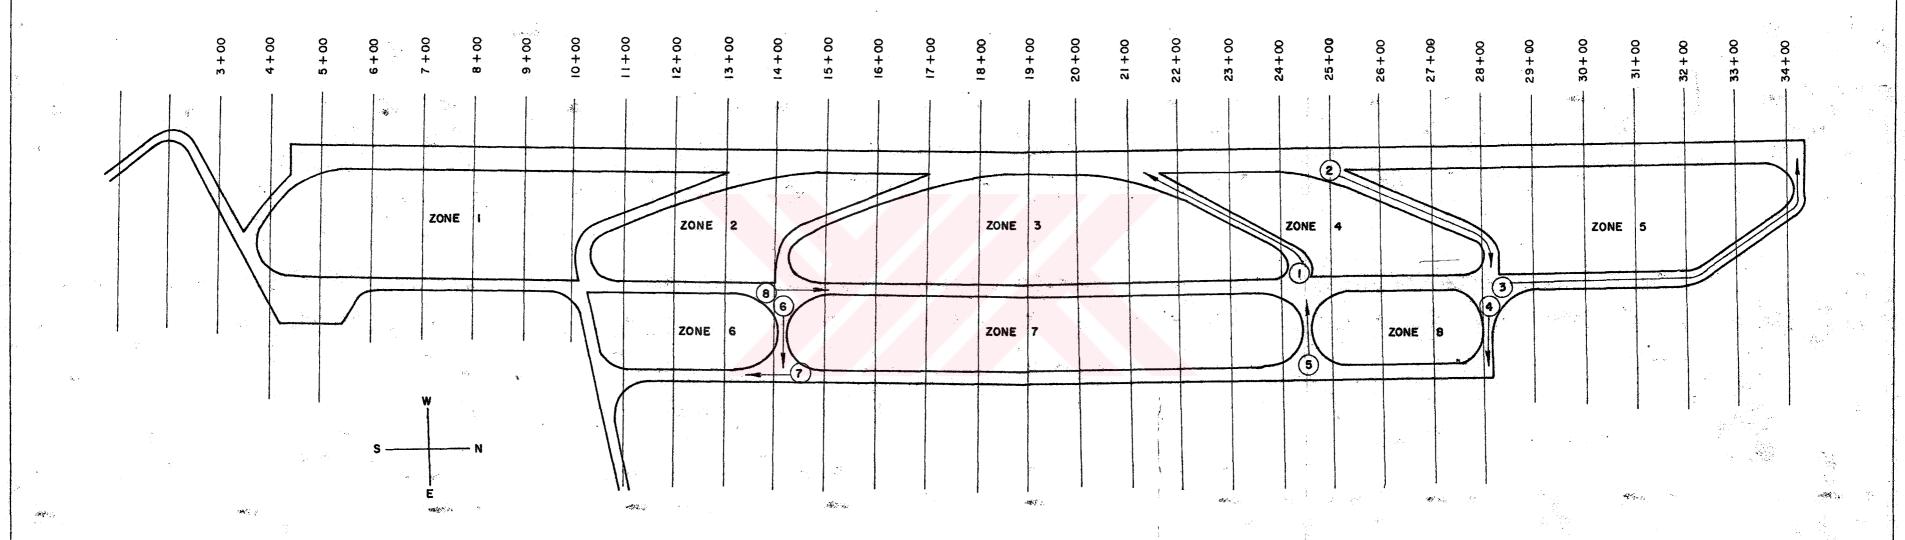

FIGURE 20: WORK FLOW LINE FOR "LEAN CONCRETING" ACTIVITIES

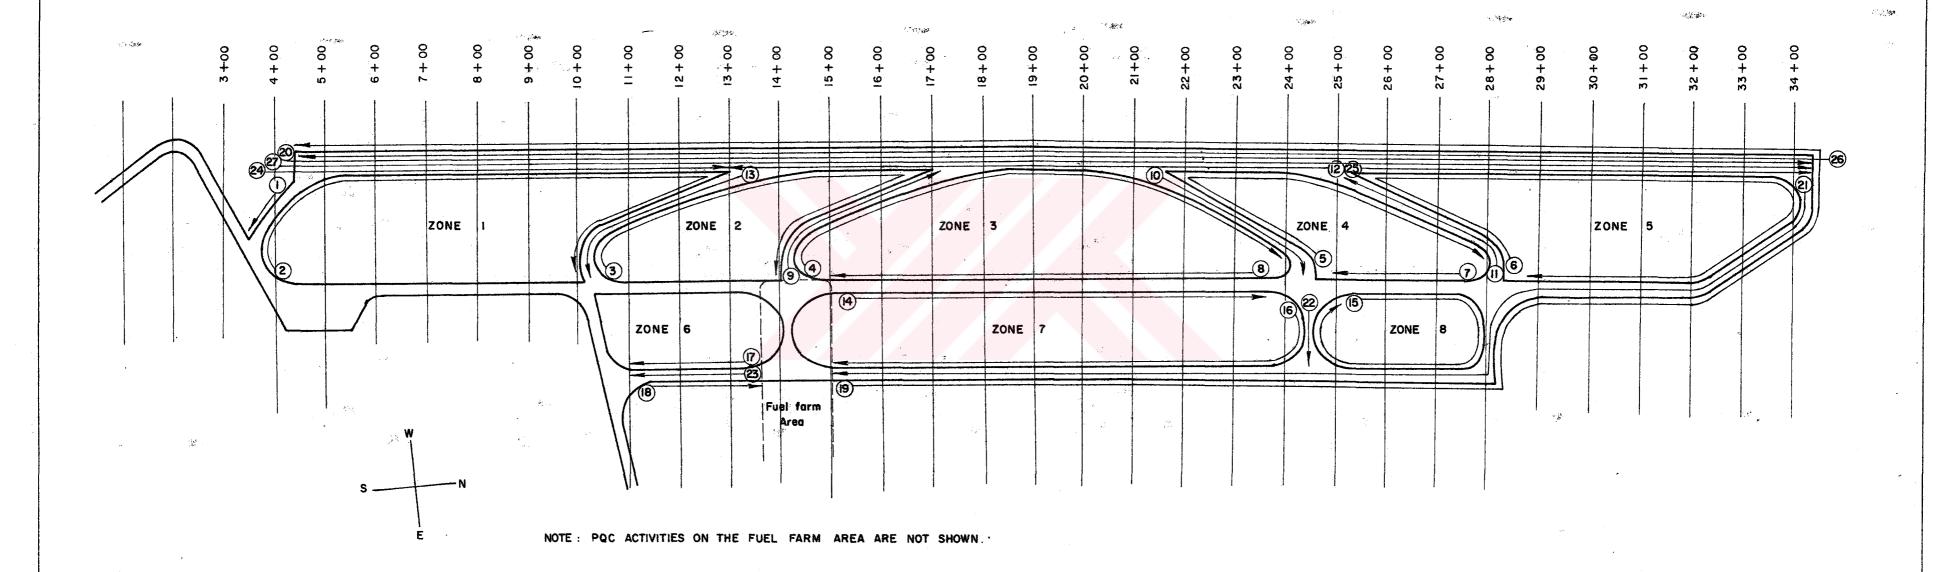

FIGURE 21: WORK FLOW LINE FOR "PAVEMENT QUALITY CONCRETING ACTIVITIES"

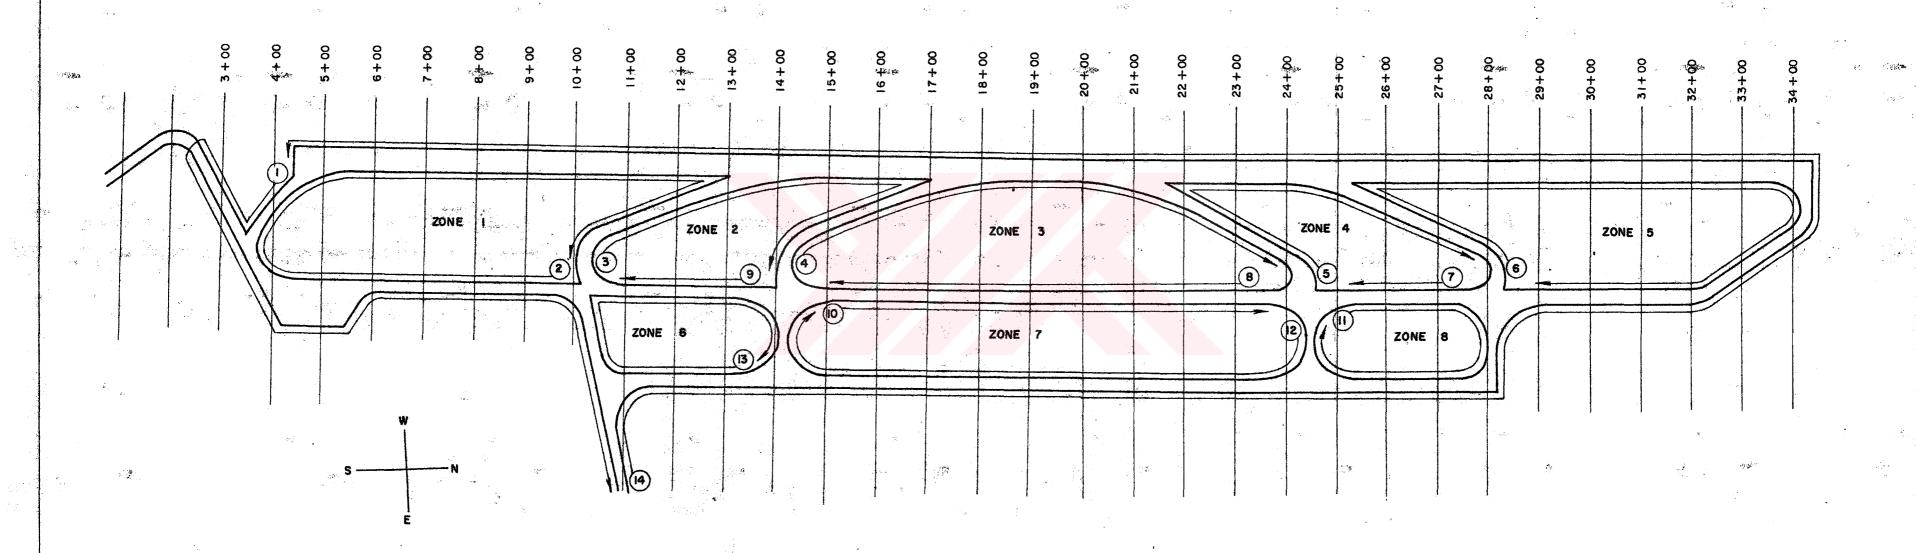

FIGURE 22 : WORK FLOW LINE FOR "SHOULDER ACTIVITIES"

vi) The flow lines are further revised, during the scheduling process. The interior strips of those pavement elements whose side strips will be completed before rain season are so scheduled that they will also be finished before rain season, in order to prevent accumulation of water between side strips.

D. DETERMINATION OF ACTIVITY DURATIONS

It is a common practice to determine activity invations after the planner has decided on specific sequencing of project activities. This is an acceptable approach, because during the sequencing process it may be found more useful to combune or to divide some activities, or to change their contents, and such an approach eliminates the need for re-determination of activity durations after each network refinement.

In general, project activities can be executed in several ways each associated with a different duration and direct cost. Some American literature (20) related to construction planning suggest that the time-cost relation for each project activity should be analyzed in detail. As the result of this analysis time-cost information obtained for each activity can be displayed in graphical or tabular form. The former one is known as "utility curve" whose theoretical and practical forms are shown in figure 23., and the latter as "utility data".

As the curves display, an activity may be performed in many different durations at the related direct costs.

Among these, the normal time is selected as the project

duration, since it gives the lowest direct cost to complete. If realistic utility curves can be developed for each project activity, then the optimum project duration which corresponds the minimum project total cost, can be determined by means of network compression or decompression computations.

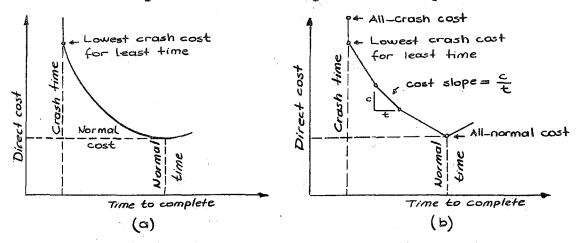

Figure 23. Time-direct cost curves for an activity

a) Theoretical curve. (b) Practical curve.

It is obvious that only a regular and continuous data collection and recording system (data bank) can enable such a detailed analysis. Since this system has never existed especially in construction industry, the estimators have no choice other than being dependent on the experience gained by the people who has involved in similar projects in the past.

As stated before, one of the major advantages of network approach is that it produces a more realistic estimate of the total length of a project, through subdivision of major elements into many smaller activities which can be estimated more accurately. This advantage can be realized properly, if dependable statistical data are provided to the planners. Therefore, data collection in

construction industry should be started immediately.

Since the project under consideration is a construction project, time estimates are assummed to be certain to a reasonable extend. The bases of duration estimates in Yeşilköy can be grouped into two:

- i) If the activity, whose duration is to be determined, is a part of a general work item some of whose activities were already finished upto the starting date of this study, the realized rate of execution is taken as the basis for time estimations. The general work items considered in this group are: Earth work, lean concreting, pavement quality concreting and constructing drainage structures. Some modification is necessarily made in the durations of PQC activities since the realized rate of execution was too slow to meet the requirement of the contract.
- ii) The estimates of the experienced competent personnel of both contractor and public owner, are accepted to be essential for duration estimation of the activities of other general work items. These estimated durations are revised when different rates of execution were observed of their commencement.

The activity durations computed by dividing the volume of work to be done by the rate of execution are given in activity list of Appendix A.

Table 2. Daily Execution Rates of General Work Items

	Daily
General Work Item	Rate of Execution
Earth Work	18000 m ³
Lean Concreting	250 m ³
Pavement Quality Concreting	700 m ³
Constructing Drainage Structures	150 m
Shoulder Stabilization	375 m ³
Forming Asphaltic Concrete on Shoulders	200 m [×]
Laying PVC Cable Passes under Shoulders	265 m [×]
Laying Multi-cell Cable Passes under Shoulders	175 m [×]
Top Soiling	1400 m ³

^{*} in terms of shoulder length.

In some projects, the durations of activities may be uncertain. This is true especially for research and development projects many of whose activities have never been carried out before or have been carried out only a few times under very different circumstances. In such cases the uncertainty involved must be introduced into activity and project durations. The Program Evaluation and Review Technique (PERT) is the result of this need. PERT uses an activity duration called "the expected mean time" (t_e) with an associated measure of uncertainty either as standard deviation ($\sqrt[]{t_e}$) or variance ($\sqrt[]{v_{te}}$).

The expected mean time is intended to be a time estimate, having approximately 50% chance to overrun and 50 % chance to underrun the actual duration realized. (Figure 24). Three estimates of activity's duration enable the determination of the expected mean time, as well as the standard deviation and the variance:

- Optimistic time (t_a) estimate is the estimate of the shortest possible time in which an activity can be completed under optimum conditions. The optimistic time estimate assumes that the activity will be accomplished in an ideal environment, free of even normal amount of delays and setbacks.
- Pessimistic time (t_b) estimate is the estimate of the longest time that it may take for its accomplishment taking all possible delays and setbacks into account.
- Most likely time (t_m) estimate is the estimate of the mean time of completion if the activity were repeated a number of times under almost the same conditions.

Mathematical expressions for the expected mean time, the standard deviation and the variance are given as (21):

The expected mean time :
$$t_e = \frac{t_a + 4t_m + t_b}{6}$$

The standard deviation : $\int_{t_e}^{t_e} = \frac{t_b - t_a}{6}$

The variance : $v_{t_e} = \frac{t_b - t_a}{6}$

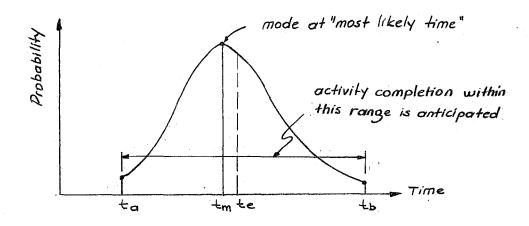

Figure 24. Probability distribution (β) curve for activity durations.

E. CODING THE ACTIVITIES

In arrow diagrams activities are identified by
the numbers of their tail and head events. There is a rule
that is commonly obeyed while numbering the events of a
network which can be stated as: "the number at the tail
of any arrow should be smaller than the number at the head
of the arrow". The simple procedure to satisfy this
requirement is: "start by labeling the first event and
proceed forwards by assigning a larger number to the
events to which tails—numbered arrows come". Some
advantages of this coding technique are:

- Selection is immediate; by looking at the diagram it is easier to pick out numbers than words on arrows;
 - Reference is abbreviated, but exact;
- Sequence is immediately evident; for example the activity (I, J) is preceded by all activities which have I as their head event number and followed by those which have J as their tail event number, and is concurrent with all those activities having I as their tail event number.

The activities in precedence diagrams are identified by their own codes. Activity codes may be numeric or alphameric. There is no rule to be followed in labeling the activities, therefore the planner should take the advantage of this flexibility. Each numeric or alphabetic character in the code of an activity may be use to denote something meaningful. For instance, the activities in the precedence diagram of Yeşilköy Airfield Infrastructure Project are coded by paying attention to two points:

- i) First numeric character after zero indicates the number of the general work item in which the activity concerned takes place.
 - ii) Last two numbers are used as location references.

CHAPTER V

NETWORK COMPUTATIONS

A. BASIC NETWORK COMPUTATIONS

The computational producedures of network based planning methods differ from each other depending on the type of diagramming technique used in constructing the network model. Therefore the procedures for arrow and precedence diagrams will be described separately. The procedure to be followed in PERT, which is a probabilistic system, will be explained briefly as a part of the procedure of arrow diagrams.

There are three main steps in network computations: which are common to both diagrams:

- i) forward pass computations,
- ii) backward pass computations,
- iii) float analysis.
 - 1. Arrow Diagrams
 - a. Critical Path Method
 - i) Forward Pass Computations

If the network is in the form of an arrow diagram the step of forward pass computations involves the computation of earliest possible occurence time (EPOT= $\mathbf{T}^{\mathbf{E}}$) for each event. The earliest possible occurence time for an event, may be defined as the time taken to complete all activities on the most time consuming path from the start of the project to the event under consideration.

The first thing to do in forward pass computations, is to assign an EPOT to the first event of the network. It is a common practice to assume the project base date or EPOT of the first event as zero, and to compute EPOTs of other events in terms of an appropriate time unit. The other alternative is to set the project base date as a calender date and then to compute the EPOT of each following event in calender dates. But this may cause some errors in computations due to holidays and non-working days involved.

As the two possible cases illustrated below clearly indicate, to compute the EPOT of an event the EPOTs of all events from which an arrow comes to that event must be known.

Case 1. When a single activity terminates at the concerned event, its EPOT is determined by adding the duration of the terminating activity to the EPOT of the preceding event.

$$T_{J}^{E} = T_{I}^{E} + t_{ij}$$

Figure 24. Single activity terminating at event J.

Case 2. When there are more than one activity terminating at event J, the EPOT of this event is determined by selecting the largest number (or latest date) among the EPOTs computed assuming each activity as the only activity terminating at that event.

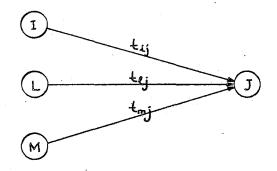

Figure 25. More than one activity terminating at even J.

The forward pass computations end when the EPOT for the last event of the network is computed.

11) Backward Pass Computations

Then backward pass computations start which involve the determination of latest permissable occurence times (LFOT = T^L) for network events. The latest permissiable occurence time for an event is the maximum time available for the completion of the activities, terminating at that event, without causing any delay in total project duration.

The LPOT for the last event of the network must be determined in order to start with backward pass computations. The common practice is to assign the EPOT of the last event to it as its LPOT. But when the permitted duration is more than the EPOT value for the last event, this may be accepted as LPOT for the last event. If the directed project duration is less, then this value may be assigned to the last event as its LPOT value. The last two cases may prevent precise network enalysis, since the first one will give positive floats even on the critical path and in the second, the planner will have to deal with negative floats. If the pre-assigned project completion date is different than the EPOT of the last event

and if the former must be met, the planner may employ network compression or decompression technique, which will be mentioned later in this chapter, for this purpose.

Case 1. When a single activity starts at the event under consideration, its LPOT is determined by subtracting its duration from the LPOT of the succeding event.

$$T_{r}^{L} = T_{s}^{L} - L_{ij}$$

Figure 26. Single activity starting at event I

Case 2. When there are two or more activities starting at an event, its LPOT is determined by selecting the smallest number (or earliest date) among the LPOTs computed assuming each activity as the only activity starting at that event.

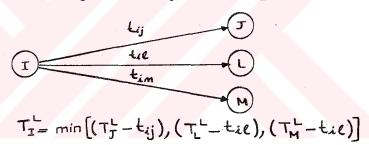

Figure 27. More than one activity starting at event I

After the completion of backward pass computations, the critical path(s) which is commonly defined as the most time consuming path through the network, can be determined.

An event lies on the critical path if its EPOT and LPOT are identical. Obviously any delay in satisfying such an event will cause project delay. For an activity to lie on a critical path two conditions must be satisfied:

- Its both head and tail events must be critical.

- Its duration must be equal to the difference in event times of the head event and the tail event.

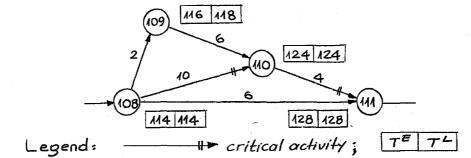

Figure 28. Critical activities on a network portion In the network portion given in figure 28. the activities (108-110) and (110-111) are critical where the activity (108-111) is not, since it violates the second condition.

Critical path is one of the major factors which makes the network based methods superior to conventional planning methods, since it clearly indicates the activities which must be kept on time in order not to cause any delay in project completion.

iii) Float Analysis

There are a variety of float measurements whose definitions and formulas are given below:

Total float (TF) is the spare time available to complete a particular activity, when all preceding activities are completed at the earliest possible times and all succeding activities start at the latest possible times.

$$TF_{ij} = T_J^L - (T_I^E + t_{ij})$$

Free float (FF) is the spare time available when all preceding activities end at the earliest possible times and all succeding activities start at the earliest possible times.

Interfering Float (IF) is the spare time available for the completion of an activity after its FF is fully consumed. Therefore if any part of IF is consumed, it will be necessary to reschedule all the following activities in that chain. If the IF is fully used, subsequent activities in the chain will become critical; if it is exceeded the project duration will be increased.

$$IF_{ij} = TF_{ij} - FF_{ij}$$

Independent float (IND.F) is the amount of time that an activity may be delayed, regardless of the state of the preceding and succeding activities within the project, without affecting the project duration.

IND.
$$F_{ij} = T_J^E - (T_I^L - \epsilon_{ij})$$

Scheduled Float (SF) is the amount of extra time that the planner specifically assigns to an activity for suitable scheduling of the project.

b. Program Evaluation and Review Technique

Although the time analysis of an activity requires the evaluation of three time estimates from which the expected mean time, standard deviation and variance are computed, in PERT computations only the expected mean time and the variance of each activity are used, since this is sufficient to introduce into the network diagram the uncertainty of each individual activity. Because a single time estimate is used, PERT network calculations differ from the corresponding CPM

calculations only in the introduction and handling of activity variances.

1) Forward Pass Computations

In forward pass computations expected earliest event occurence times (T_{xe}) are computed. In addition to this, variances of expected earliest event times (v_{Txe}) are determined by summing up the variances of expected activity mean times along the most time consuming path leading to the event under consideration.

11) Backward Pass Computations

In backward pass computations, in addition to expected latest event occurence times $(T_{\rm xl})$ which are computed in exactly the same way as LPOTs in CPM calculations, the corresponding event variances $(v_{\rm Txl})$ are derived, starting from the last event of the network and assigning zero variance to it. Then other event variances are found by adding up the variances of expected activity mean times following the path which was followed in the computation of expected latest event times.

Two variances are now applicable to each event V_{Txe} and V_{Txl} . The first measures the uncertainty in the most time consuming path up to the event under consideration; and the second measures the uncertainty still to be encountered along the longest time path from this event to the project completion.

iii) Slack Analysis

For some events the T_{xe} and T_{xl} values are different; this difference is called "event slack" and mathematically

expressed as:

Event Slack = Txe-Txe

Slack in PERT calculations corresponds to the total float consept in CPM and it is a measure of flexibility available in project schedule. Therefore an event with zero slack must lie on an expected critical path. An activity whose head and tail events are critical, lies on the critical path, if its duration is equal to the difference between its head and tail event times.

Once the expected mean time for an event (T_x) and its standard deviation $(\overline{T_t})$ are determined, it is possible to calculate, from probability theory, the chances of meeting a given "event scheduled time" (T_s) . To do this, the event completion time is assumed to have a normal probability distribution with the mean value T_x and a standard deviation $\overline{T_t}$ determined as before by summation of individual activity beta-distribution curves. This hypothesis implies that the effect of adding a series of independent beta-distribution curves gives a normal-distribution curve; this is true only for an infinite series, but is approximately true in practice with reasonable sized networks.

To calculate the chances of meeting the time T_s , the practical approach is to use the standard probability tables prepared for normal distribution functions, of which a condensed one is given in table 3. To use this approach, the difference between the scheduled and expected mean times for the event is scaled down to a normal distribution curve, by computing a factor Z, where:

$$Z = \frac{T_s - T_x}{\sqrt{T_x}}$$

Using the computed value of Z, a direct entry into a standard probability table gives the probability of meeting the scheduled time $\mathbf{T}_{\mathbf{s}}$.

Similarly, the scheduled time for an event can be determined for a given risk level,

$$T_s = T_x + Z \int_{Tx}$$

where the value of Z is obtained from standard probability tables for a given probability or risk level.

Table 3 Approximate Values of the Standard Normal Distribution Function

Z	Probability	Probability	Z
-2.0	0.02	0.98	+2.0
-1.5	.07	۰93	+1.5
-1.3	.10	۰90	+1.3
-1.0	.16	.84	+1.0
-0.9	.18	.82	+0.9
-0.8	.21	.79	+0.8
-0.7	. 24	.76	+0.7
-0.6	.27	•73	+0.6
-0.5	.31	.69	+0.5
-0.4	· 34	.66	+0.4

-0.2	.42	. 58	+0.2
-0.1	.46	.54	+0.1
0.	•50	.50	0.

- 3. Precedence Diagrams
- 1) Forward Pass Computations

If the network is prepared as a precedence diagram, earliest start (ES) and earliest end (EE) times of activities are obtained as the results of forward pass computations. In this case the computation is started by setting an earliest start date for the first activity of the network, then ES and EE of other activities are determined. The existence of aforementioned three relation types and their possible combinations cause difficulties in network computations. For this reason each possible case will be illustrated separately in order to prevent any probable misunderstanding.

Case 1. When the activity under consideration has a single predecessor:

- The activity is related to its predecessor by a single relation

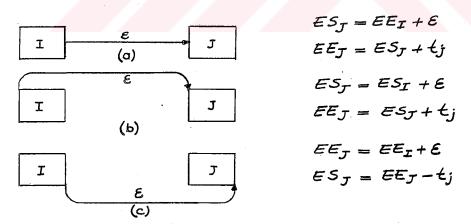

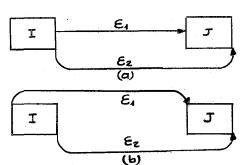

Figure 29. Activity J is related to its predecessor by a single relation

(a) E-S (b) S-S (c) E-E

- The activity is related to its predecessor by more than one relation.

$$ES_{J} = max [(EE_{I} + \epsilon_{i}), (EE_{I} + \epsilon_{z} - t_{j})]$$

$$EE_{J} = ES_{J} + t_{j}$$

$$ES_{J} = max [(ES_{I} + \epsilon_{i}), (EE_{I} + \epsilon_{z} - t_{j})]$$

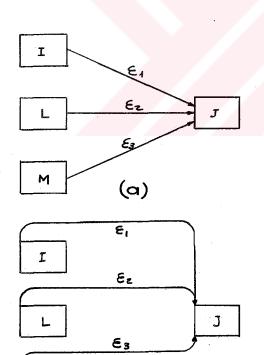

$$EE_{J} = ES_{J} + t_{j}$$

Figure 30. Activity J is related to its predecessor by a combination of two relation types:

(a) E-S and E-E, (b) S-S and E-E

Case 2. When the activity under consideration has more than one predecessor:

- The activity is related to its predecessors with the same relation type.

(P)

$$ES_{J} = max \left[(EE_{I} + E_{i}), (EE_{L} + E_{c}), (EE_{M} + E_{3}) \right]$$

$$EE_{J} = ES_{J} + \ell_{J}$$

$$ES_{J} = max[(ES_{I} + E_{i}), (ES_{L} + E_{z}), (ES_{M} + E_{s})]$$

$$EE_{J} = ES_{J} + E_{j}$$

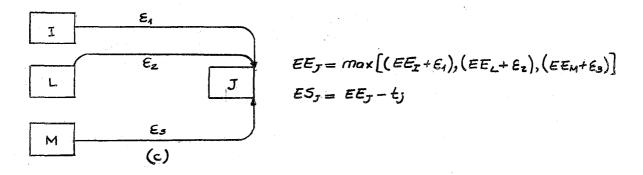

Figure 31. Activity J is related to its predecessors with same relation type:

(a) E-S, (b) S-S, (c) E-E.

- The activity is related to its predecessors with different relation types.

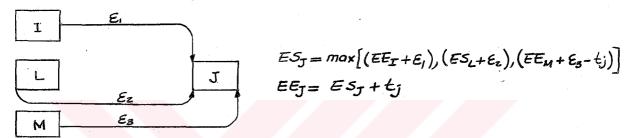

Figure 32. Activity J is related to its predecessors with defferent relation types.

- The activity is related to each of its predecessors with more than one relation type.

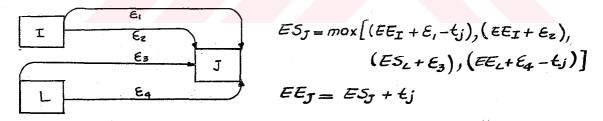

Figure 33. Activity J is related to its predecessors with combinations of two different relation types.

After the illustration of the cases which are likely to be faced while performing forward pass computations in precedence diagrams, attention should be drawn to the point that when the start of an activity is not related to any of its predecessors, although it may be thought that its ES is the project base date, ES should be taken as the difference between EE and duration of the activity in order to secure its continuity.

ii) Backward Pass Computations

Forward pass computations end when the ES and EE of the terminating activity are determined. At that point backward pass computations start which aim the determination of latest start (LS) and latest end (LE) times for project activities. The first step of these computations is setting the LS and LE of the last activity equal to its ES and EE respectively. The cases that the planner will possibly be faced while performing backward pass computations are illustrated below:

Case 1. When the activity under consideration has a single successor.

- The activity is related to its successor by a single relation type.

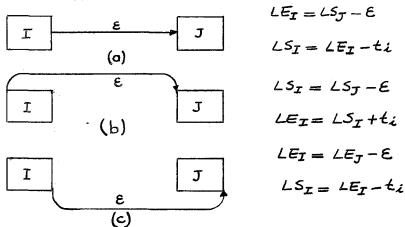

Figure 34. Activity I is related to its successor by a single relation (a) E-S, (b) S-S, (c) E-E.

- The activity is related to its successor by more than one relation type.

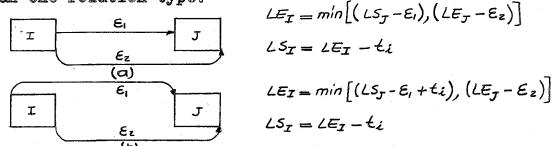

Figure 35. Activity I is related to its successor by a combination of two relation types:

(a) E-S and E-E, (b) S-S and E-E.

Case 2. When the activity under consideration has more than one successor.

- The activity is related to its successors with the same relation type:

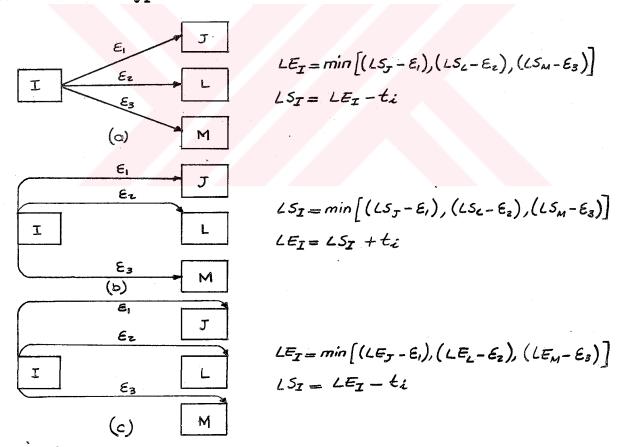

Figure 36. Activity I is related to its successors with same relation type (a) E-S, (b) S-S, (c) E-E.

- The activity is related to its successors with different relation types.

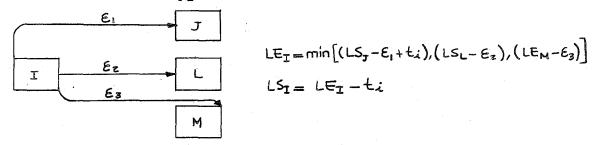

Figure 37. Activity I is related to its successors with different relation types.

- The activity is related to its successors with more than one relation type:

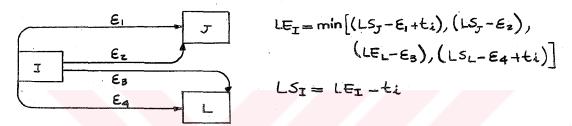

Figure 38. Activity I is related to its successors with combinations of two different relation types.

Backward pass computations end when the LS and LE times for the first activity of the network are determined. In backward pass computations it should be pointed out that when the end of an activity is not related to any of its successors, its LE should be taken as the summation of its LS time and duration, but not the project end date.

iii) Float Analysis

The determination of critical path(s) and analysis of floats is the next step. Keeping the definitions of floats the same as given before, their mathematical expressions are modified as:

Total float (TF)

Activities having zero total float will appearantly take place on a critical path.

Free float (FF) of an activity cannot be formulated by a single expression due to various relation types in precedence diagrams. The formulas for three possible cases are given below. If the activity whose FF will be computed, is related to more than one succeding activity with various combinations of relation types, each relation will be considered individually and free float due to each single relation will be computed separately, then the minimum of them will be assigned to the relevant activity as its free float.

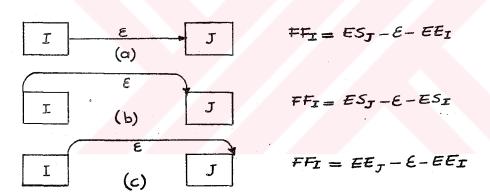

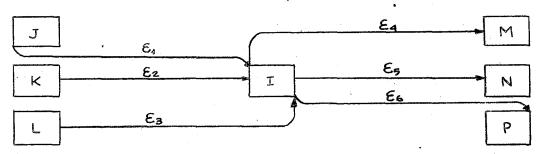

Figure 39. Activity I is related to its successor by

(a) E-S, (b) S-S, (c) E-E relation types.

Interfering float (IF)

Independent float (IND.F) may also be defined as the maximum additional time that can be made available for the accomplishment of an activity such that all of its predecessors

will end at latest permissible times and all of its successors will start at earliest possible times. A general case is illustrated below; if the activity under consideration has more successors and predecessors, or more than one relation type exist between the activity considered and its predecessors or its successors, individual float may be calculated by taking relations into account one by one.

IND.F_I = max
$$[(LS_M - \varepsilon_4 + t_i), (LS_N - \varepsilon_5), (LE_P - \varepsilon_6)]$$
 - min $[(ES_J + \varepsilon_1), (EE_K + \varepsilon_2), (EE_L + \varepsilon_3 - t_i)]$

Figure 40. Independent float of activity I.

B. ROLE OF COMPUTER IN NETWORK CALCULATIONS

The mathematical structure of networks make them suitable for electronic data processing. All necessary time, cost and resource computations can thus be performed by computers.

In this section, the major considerations involved in deciding to use the computer, advantages and some problems faced in using them will be described.

In general, computers are preferred to manual computations when they cost less. But in cost calculations, irreducible factors like the value of time must be carefully analyzed since early warnings may affect the profit

appreciably. For instance there may be a case in which manual computation costs less than computerized one, but if the computerized system supplies information to managers weeks before than they would otherwise get, the use of computer becomes preferrable.

1. Factors of Using Computers

There are "several factors to be considered in deciding whether or not to use computer for network computations. These are:

- a. Network Type- Arrow diagrams are more suitable for manual computations than precedence diagrams are.

 Because the various relation types and lag values involved in precedence diagrams may cause errors or at least inaccuracy and time loss as the number of activities goes above hundred.
- b. Network Size and Complexity It is a common practice to express the network size by the number of activities in it. The degree of complexity may be determined by the number of relations between the project activities and their types. In deciding whether or not to use computer, size and complexity of the network should be considered. It is advisable to use computer if the network is composed of at least few hundred activities, unless it is a very simple one such as a network with long independent paths.
- c. Degree of Detail in Data In addition to activity decriptions and durations, the planner may wish to deal with cost and resource informations. Also, if the

selected planning method is PERT or any version of it, three time estimates for each individual work item, which are to be known for the calculation of expected mean time, standard deviation, variance and probabilities of meeting the scheduled completion dates, becomes an integral part of the data. As the data becomes more detailed to perform the required network calculations, the use of computers becomes favorable.

- d. Types of Reports Required Computer programmes provide managers with various types of reports which are prepared in detail. For example, Project Control System (PCS) of IBM can produce 14 different types of output reports. If only the earliest and latest, start and end times, and total floats of activities are required; and if consideration of other factors results in favor of manual computations the planner may prefer to prepare the reports manually.
 - e. Updating Frequency If a network is to be analyzed only once and never updated to monitor progress, manual analysis can be justified even if the network is a large one. Because the preparation of data for only one computer run may take more time than manual analysis. But if the network is to be updated frequently, the use of computer may become profitable.
- f. Periodicity of Reports The results of a network analysis should be made available to managers periodically. Time consuming manual methods compare unfavorably with computer except on small and simple networks.

g. Formality of Reports - If the network analysis results are to be used by the planner himself or by a few persons in an informal manner, all calculations may be shown on the network diagram itself. Computer processing with multiple copies, eliminates the need of preparing formal reports for different partners. They can even be used as contract documents.

In many cases, manual computations to find the critical path at the beginning of planning works is very useful for the logical refinement of the network. It is obvious that this will be a very tedious work especially if the network is large and complex. But, since the logical refinement will change duration and cost estimates, and even the activity codes and descriptions, this procedure eliminates the time loss, cost and difficulty involved in changing the input data of computer program until it is completely refined.

2. Benefits of Using Computer

a. Speed - The computer perform calculations considerably faster than a person. For example IBM/7030 needs only one second for 400 000 multiplication operations where a person can perform only one multiplication in 60 seconds (32).

The speed of computer enables the submission of network analysis reports to managers in exact periods of time.

- through calculation and data manuplation processes.

 Therefore output reports of a computer process are more dependable than those obtained by manual manuplations.

 But errors may occur in preparing input data, some of which are diagnosed by editing and self-checking features built into well-designed computer programs. Since logical faulty in input data will cause erroneous results, the network should be carefully refined; and also the planners must analyze the results to ensure the correctness of input data.
- e. Economy As the size and complexity of the network model increase, the use of computer becomes more economical than manual systems. The cost saving grows rapidly as the volume of data increases beyond the breakeven point which is quite hard to define due to irreducible factors involved.
- d. Ability to Handle Large Volumes Network based planning systems are accepted to be superior to other systems due to several reasons one of which is enabling very detailed project breakdown, thereby making possible to estimate duration and costs of activities more accurately. But detailed breakdowns result in large volume of data which are very difficult to handle without computers. For instance Project Control System of IBM/360 can process networks upto 5000 activities which are impracticable to analyze manually.
- f. Uniform Format of Reports A computer with a well-designed program matching the network based system

introduces dicipline and standardization to reporting system. This increases the efficiency of the management.

- 3. Problems Faced in Using Computer
- a. Over-estimation of Computer Capability Many people, including some managers who do not have a clear idea what the computer can and cannot do, expect more from the computer than it is possible to get. Consequently they get disappointed, when they acually use the computer.
- b. Strict Dicipline The computer imposes a strict dicipline which is quite hard to become accostumed. It requires all necessary data to be provided and to be entered properly and precisely. The computer detects errors in input data and return them for correction; this may cause delay, where in manual systems if any missing information or errors are detected they can be corrected before proceeding further.
- c. Administrative Problems A bureaucracy grows up around computer, calling for forms to be filled out and for approvals to be obtained. If an error is detected in data, even though it may take only a few minutes to correct it, at least 24 hours are needed for a new try at computer. This time consuming procedure may cancel out some of the advantages gained due to the speed of computer.

C. COMPARISON OF PCS AND BKN

PCS and BKN are the two available computer programs for network analysis. The network model of Yeşilköy Airfield Infrastructure Project has been analyzed by both of them, and the reports obtained are submitted in Appendix C. The preparation of input data and output reports are discussed in Appendix B.

In this part these two programs will be compared in various aspects. Before going into detail, it should be pointed out that PCS is a complete program; whereas BKN is composed of a main part, computing the work schedule, and additional ones to be used with the basic part. Most of these programs are not available yet in Fortran language.

1. Activity

a. Identification and Description

In both systems activities of a network are identified by their identification codes and described in such a way that they will not be confused with any other activity in the network.

- PCS permits the user to use 10 alphameric characters for each identification code, and 44 alphameric characters for each activity description (see "Work Item Card", Appendix B.1)
- BKN permits the user to use 10 numeric characters for identification codes and 30 alphameric characters for descriptions (see "Activity Description Card", Appendix B.2)

b. Duration

- In PCS activity durations are specified as decimal numbers carried out to tenths; and the user is allowed to use 7 different time units which are internally converted to days: days, hours, half-days, one-shift days, two-shift days, three-shift days and weeks (see "Work Item Card" Appendix B.1). In addition, the number of hours in a day can be entered (see "Processing Control Card", Appendix B.1).
- In BKN each activity can be assigned a duration which has to be expressed in whole days (see "Relation Card", Appendix B.2).

c. Cost

- PCS produces two cost reports, lump sum and monthly cost, using three different categories of cost: total estimated cost, actual cost of this period and actual cost to date.

Total estimated cost is a seven digit number that represents the estimated number of whole dollars it will cost to perform the activity. The user may specify total estimated cost for an activity using the resource cards (see "Resource Card", Appendix B.1).

Actual cost of this period is a seven digit number representing the number of whole dollars spent in performing an activity during the current reporting period (see "Progress Reporting Card", Appendix B.1).

Actual cost to date is a seven digit number that represents the number of whole dollars spent in performing an activity since work on that activity has started (see

"Progress Reporting Card", Appendix B.1).

- For cost analysis a special BKN program should be employed (see "BKN-COST", Appendix B.2.II).

d. Resource

- PCS can perform some computations related to resources and produces two reports: Resource Assignment Report and Resource Utilization Report (Appendix B.1.II)

A resource element is defined as the number of whole units of the resource required to perform the relevant activity and is identified by a resource code.

A resource element may be specified as the number of units of the resource required to perform the relevant activity for the period of one unit time or for the duration of that activity (see "Resource Card" Appendix B.1).

- For the analysis of the resource aspect of a project, there is a special BKN program (BKN- POT) which is briefly described in Appendix B.2.II.

e. Float

- PCS computes two types of float for each activity: start float and completion float. The start float is the number of days between the early and late start dates and the completion float is the difference between the early and late completion dates. Both of them are printed as decimal numbers carried out to tenths of a day (see "Schedule Report", Appendix C.1).

In fact both of these floats are identical to total float unless there exists a time blockade area. In computing these float values PCS considers holidays and special nonwork

days in addition to working days.

- BKN computes two different floats for each activity: gross (total) float and free float. These float values are printed in schedule report in terms of whole days (see "Schedule Report" Appendix C.2). BKN considers only working days in float computations.

f. Milestones

- In PCS the start or the completion of an activity whichever is of major interest or importance to the project may be specified as a milestone. Upto 480 milestones may be specified (see "Milestone Card", Appendix B.1). Once the user has specified Milestones for a network, he may obtain a Milestone Report that shows the dates PCS calculates for each of them.
- No milestone can be specified in BKN program.

 But, a general network with major activities may be prepared at the beginning of work, and controlled during the project execution for the same purpose.

g. Exogene Dates

- PCS allows the user to specify one of five different types of scheduled date for an activity (see "Schedule Card", Appendix B.1):
- Type 1. These dates have no effect on the system

 Type 2. This represents the earliest date desired

 for PCS to schedule the start or the completion of an

 activity.
- Type 3. This represents the specific date desired for PCS to schedule the start or the completion of an

activity, regardless of the early or late start or completion dates the system computes.

Type 4. This fixes the late start or completion of an activity on a desired date.

Type 5. This sets the late completion time of the work item equal to the calculated early completion time.

- BKN permits the user to fix either the start or completion of an activity on a desired date (see "Exogene Date Card", Appendix B.2). If the start of an activity is fixed, its both early and late start times are set equal to that scheduled date. Similarly early and late finish times of an activity are taken equal to the scheduled date on which the completion of the activity is desired to be fixed.

2. Network

- a. Type
- PCS is designed to process procedence networks.

 However if the network submitted is an arrow diagram, it internally converts it into precedence diagram (see "Processing Control Card", Appendix B.1).
 - BKN processes only precedence networks.
 - b. Size and Complexity
- PCS can handle networks upto 5000 activities.

 The maximum number of preceding activities can be 12 500.
- The available BKN program can process networks upto 2199 activities and 4199 relationships.

c. Relationships

The relationships that exist in a network are the dependencies that exist between various activities contained in the network.

- PCS accommodates three different relationships (see "Preceding Work Item Card", Appendix B.1).
 - i) Start to start,
 - ii) End to end,
 - iii) End to start.

The user of PCS may specify more than one relationship for the same pair of activities, as long as no two relationships are of the same type. If more than one relationship is specified for the same activity, PCS uses the relationship that produces the longest time delay.

- All types of relationship processed by PCS, can also be handled by BKN. But the relationships are categorized in a different manner (see "Relation Card", Appendix B.2):

Type O. End to start with no time delay,

Type 1. End to start with some time delay,

Type 2. Start to start,

Type 3. A combination of start to start and end to end,

Type 4. End to end.

In recently developed BKN programs type 0 and type 1 relationships are combined and called as type 0, for which time delay may be zero or greater than zero. In these programs type 1 is "start to end" relationship which does not exist in PCS.

In BKN a single type of relationship can be set for the same pair of activities. When type 3 relationship is set between two activities the system determines the relation producing a longer time delay, and uses it for computations.

d. Time Delays

The time delays, in both systems, are the amount of minimum time distance required between:

- i) The start of one activity and the start of a previous activity in a "start to start" relationship.
- ii) The completion of one activity and the completion of a previous activity in an "end to end" relationship.
 - iii) The start of one activity and the completion of a previous activity in an "end to start" relationship.
 - PCS permits the user to specify a time delay either in time units in which the duration of the base work item (preceding activity in "start to start" and "end to start" relationships, and succeding activity in "end to end" relationship)or as a percentage of the estimated duration of that base work item. The user is allowed to change the base work item if he wishes.

Whenever a time delay is assigned for either "start to start" or "end to end" relationship, the working days of the base work item are considered for the passage of this delay, but in "end to start" relationship, holidays and special nonwork days are also utilized.

- In BKN system the user has to specify time delays only in whole days. The days of the calender submitted to the system are considered for the passage of time delays.

A new version of BKN program permits the user to specify maximum time distances, required between project activities, regardless of the existing relationship type, providing flexibility in planning.

e. Calender

- PCS allows activities to be subjected to any of these three calenders (see "Calender Card", Appendix B.1):
- i) Standard Calender- A normal year of 365 days, leap years having 366 days.
- ii) Holiday Calender- The standard calender, less specified holidays.
- iii) Special Calender The standard calender less specified holidays and specified nonwork days.

In addition, the work week specification provides for the exclusion of specific days of the week for an activity (see "Work Item Card", Appendix B.1).

Since the standard calender is already contained within the system, the user specifies only those days to be deleted from the standard calender (see "Calender Card", Appendix B.1).

- In BKN only one calender can be assigned to all activities of the project. The user specifies the days on which work will be scheduled, using the calender cards described in Appendix B.2.

f. Critical Path

- PCS does not print out the critical activities.

The critical activities can be observed either from bar

chart" on which their durations are shown by special marks (see "Bar Chart", Appendix C.1) or from "Schedule report" since activities on the critical path have zero total float. But for some critical activities PCS may compute float values slightly greater than zero (see "Schedule Report" Appendix C.1).

- BKN program provides the user with a list of critical activities. Also the status of a critical activity is reported as:

Normal- If compression of an activity causes a reduction in the project duration, it is called as a normal critical activity. No remark is made for these activities.

Neutral—The critical activities are classified as "neutral" if their compression do not yield any reduction in the duration of the project. An example of neutral critical activity is the activity 0906 in the network model presented in Appendix E.

Negative- The critical activities having this message beside their identification codes are of great significance, because the project duration will be prolonged if such an activity is compressed.

3. Input

All input data are to be submitted in form of card images to both of these programs. The types of input cards and their formats are described in detail in Appendix B.

On update and maintenance runs PCS requires the specification of only those information which are to be

added to or deleted from the data submitted to the system on a generation run. But for this purpose a special permission to occupy the storage of the computer must be obtained. This is not permissable in most cases.

If the user employs a special version of BKN programme (see "BKN-MOD", Appendix B.2.II), he can load all necessary information about a network on a tape, then make all necessary modifications on that network.

When only schedule report and bar chart of a project are required, BKN requires more input cards than PCS mainly because activity description cards are submitted twice in BKN, one set being for schedule report and the for bar chart. In addition, the user of PCS can specify upto three relationships on a single preceding work item card, if the network is designed as a precedence diagram, where BKN requires the submission of a different relation card for each relationship.

On the other hand, as the descriptions of the programs given in Appendix B clearly show, the rules to be obeyed are more detailed and the formats to be followed are more complex in PCS than those in BKN.

4. Output

Both systems can produce their reports either in working days or in calender dates. But the "working day" term has been used to mean different things for each system; PCS takes the "project base (start) date" as l and assumes all days on the standard calender as working days (or project days), where BKN takes the project start

date as 0 and assumes the days on which work to be scheduled as working days.

PCS can produce 14 different reports on a single run, whereas BKN can produce only schedule, calender, critical path and bar chart reports with its basic part.

The order, in which the activities appear in schedule report and bar chart of BKN is that of the activity description cards in the input card deck.

Therefore the order of appearance of activities can be affected only by resorting the activity description cards. PCS provides a great flexibility in this respect enabling the user to have 8 different ways of activity sequencing in output reports (see "Output Request Card", Appendix B.1).

PCS uses each printing position as one day on standard calender while producing bar chart. But the user of BKN is allowed to change the scale of bar chart as he wishes (see "Scaling Card", Appendix B.2).

Although PCS produces its reports for the whole project length, it can produce some reports such as bar chart, lump sum cost, monthly cost, resource assignment, work status and progress, and schedule reports, for a desired interval of time within the project duration; where bar chart and schedule report of BKN covers the whole length of the project.

5. "Diagnostic Program Messages" (Error Messages)PCS prints diagnostic program messages to indicate

errors made in input preparation or errors discovered during network processing, or output preparation. The system is provided with detailed editing and self checking features by which almost all possible errors are located (33). The error messages printed by PCS are of four types:

i) Type R - indicates an error for which the program has attempted to make a logical adjustment. Card reading and/or processing was then resumed. There are 24 error messages of this type. Example:

ERROR 12049 TYPE R

Explanation: An invalid work week start day, cc 67 in the work item card, has been specified. The program assigned a value of 1 (Monday).

Action: Check, and if necessary, change and resubmit.

ii) Type I - indicates an error that the program has ignored. Card reading and/or processing was resumed. 66 errors that do not critically affect other data and/or processing, but for which no logical adjustment is apparent, fall into this class. Example:

ERROR 12072 TYPE I

Explanation: The scheduled start day, in cc 20-26 of schedule card, is invalid. The program ignored the date.

Action: Check the card, and if necessary, correct and rerun.

iii) Type W - indicates a warning to the user that the system has taken some type of specific action based upon a

user request. There are 3 error messages of this type. Example:

ERROR 12299 TYPE W, RPT. xx/y

Explanation: The time span of one or more work items in the network extends beyond the implied, or user-specified, upper span date from the output request card for this report. These work items will not appear on the report. The report identification is printed following the letters "RPT" in the message, where xx is one or two digits specifying a particular report, and y specifies the number punched into the output request card used to request the report.

XX	Report
4	Work Status and Progress Report
5	Schedule Report
6	Bar Chart
9	Lump Sum Cost Report
10	Monthly Cost Report
	Precedence Report

Action: If the user desires to have all work items to appear on the particular report, he should specify an upper span date greater than the calculated dates for all work items and submit a PCS report run.

iv) Type F - indicates an error that critically affects other data and/or calculations. The program may continue to read any remaining input cards in order to locate other errors, or immediately terminate the run. If an error of this type occurs during network processing, the run is always immediately terminated. There are 27 error messages in this

group. Example:

ERROR 12002 TYPE F

Explanation: No network identification code has been specified in cc 2-5 of card B.

Action: Enter the network identification code in ec 2-5 of network title card.

The error messages that may be given by BKN are:

- i) DOUBLE DURATION This message is printed out with the identification of the activity for which different durations are punched on different relation cards. The system assumes the duration that appears first in the input card deck, as the correct duration and continues processing.
- ii) STOP 1- This message indicates that the number of activities contained in the network exceeds 2199.
- iii) STOP 2- This message warns the user that he has specified more than 4199 relationships.
- iv) UNDEFINED JOB The activity whose identification code is printed next to this message has no preceding activity, although it is not the starting activity of the network.
- v) Loop The codes of activities constituting a loop are printed out. The program breaks the dependency between the last two activities of the loop and continues to search for other loops before stopping.
- vi) N CALENDER DAYS MISSING This message indicates that the submitted calender is N days shorter than the

project duration. The working day option is used for the activities taking place on those missing days.

- vii) POSITION OF CALENDER CARD N. CONTROL PLEASE- This message warns the user that the calender cards are not sorted in accordance with their sequence numbers punched on cc 79-80 (see "Calender Card", Appendix B.2).
 - D. DETERMINATION OF THE MOST ECONOMICAL PROJECT DURATION

The most economical or optimum duration for a project may be defined as the project duration which corresponds to minimum total cost. Total project cost has two components: direct cost and indirect cost. The direct project cost is the sum of all direct expenditures made in accomplishing the work. In other words, it is the summation of direct cost of all project activities. The indirect cost (general overhead cost) consists of all expenditures made for supervision and direction of the project. It is affected by bonus to be gained in case of early completion and penalty to be paid for late accomplishment as well as by interest costs, and other advantages and disadvantages related to project duration such as the time of release of the personnel and installations.

In order to determine the optimum duration for a project, the direct and indirect cost curves whose summation gives the total cost curve must be known (fig.41). In general, indirect cost curve for a project can be plotted based on the estimates of competent personnel of the firm.

But for the determination of the project direct cost curve

a complex computational procedure, which is commonly known as "network compression", must be followed.

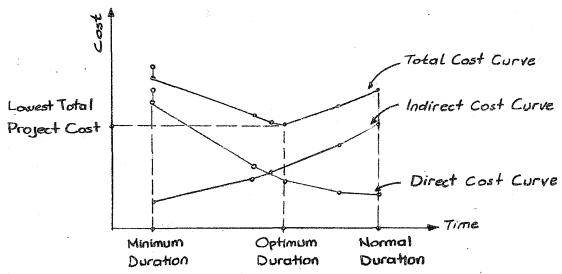

Figure 41. Most economical duration for a project.

Network compression computations involve systematic and progressive reductions in project duration through the use of additional resources, thus speeding up individual activities in economical limits. The speeding up an activity depends upon the availability of resources and the form of its utility curve, and independent of its position in the network. Therefore duration of any activity can be reduced, unless there exists some preventing physical constraints or shortage of additional resources.

Since the critical path is the longest time path through the network, only the compression of the activities, laying on the critical path, can reduce the project duration. In order to have an economical compression, the critical activity having the flattest cost slope should be selected.

Network compression calculations consist of following steps:

Step 1. The activities on the critical path are listed.

Step 2. The critical activities having zero potential for compression are excluded. These include activities whose normal and crash durations are identical as well as those already fully crashed in previous stages.

Step 3. The activity, having the flattest cost slope among the listed activities, is selected, since this will give the cheapest compression.

Step 4. The amount by which this activity can be compressed and its relevant cost are determined.

Step 5. The compression is carried out within the limitations imposed.

Step 6. The new project duration and the corresponding direct cost are determined.

Step 7. If any noncritical path becomes critical during the compression process, the activities on this path are included in the list of compressible critical activities.

Step 8. The steps 1 through 7 are carried out until any reduction in the project duration becomes impossible.

As the above explanation clearly indicates, the planner must be provided with complete information about the utility data of all project activities, if he is expected to determine the most economical project duration. But almost in all construction projects the network compression calculations are not carried out due to lack of dependable data.

The complexity of network compression calculations is directly proportional with the size and the complexity of network. If utility curves of activities are not linear and continuous, the compression process becomes extremely difficult to carry out.

E. RESOURCE LEVELING AND SCHEDULING

The schedules prepared, under the influence of physical and operational constraints, by PCS and BKN, are submitted in Appendix C.l.a. and C.2.a. respectively. In these schedules, activities of the same general work item do not overlap, because they are sequenced to form a single chain, considering the resource limitations imposed. Therefore, at this stage, the need for additional resources is eliminated. But an analysis of aforementioned reports will prove that there are some interruptions, between the subsequent activities of a general work item, causing considerable amount of idle time. The project activities have to be rescheduled now, in order to cancel out those interruptions, thereby to maintain effective flow and smooth execution of work.

In the following paragraphs the procedure followed to achieve this aim will be illustrated for each general work item of the Yeşilköy Airfield Infrastructure Project. Also, the differences between the schedule reports obtained by PCS and BKN will be explained.

i) Pavement Quality Concreting (PQC)

The schedule reports presented in Appendix C.l.a. and C.2.a have indicated that many of the PQC activities

are on the critical path. Therefore, these activities are given the priority in scheduling.

All critical PQC activities (0322 - 0329) are scheduled to start at their computed starting times. The noncritical PQC activities are scheduled to start at their earliest starting times, keeping the available floats as future safety margins.

The BKN program gives a list of critical activities (Appendix C.2.b), but PCS does not provide the planner with a list of critical activities. These activities can be seen in the schedule report, since, by definition, the activity of critical status has no total float. The reason behind the fact that some critical activities having their total floats slightly greater than zero have appeared in PCS schedule reports, can be explained by an assumption made in designing the system. This assumption may be stated as "when a time delay is assigned in an end-to-start relationship, holidays and special nonwork days are also utilized for the passage of this time delay". This assumption is not valid for the end-to-start relationships between the PQC activities, since the time delays in these relationships are used to indicate the amount of time that will be needed for shifting of equipment and team from the location of one PQC activity to that of subsequent one. Therefore only working days should have been considered for these time delays.

Another fact which can be observed at this stage is that the noncritical PQC activities have different total

floats on PCS and BKN schedule reports. The reason of these differences is the expression of activity durations and time delays in different ways. As explained in Appendix B, the user of PCS can assign durations to project activities in tenths of a day. But, in BKN, activity durations and time delays must be expressed in whole days. Therefore all time delays between the PQC activities are set equal to zero, and activity durations are rounded off while using BKN program.

ii) Lean Concreting (LC)

The LC activities whose codes are 0207, 0208 and 0201 are come out to be critical. Therefore, they are scheduled to start at their computed starting times. Then the activities 0206 and 0205 are scheduled to follow this critical chain without any interruption. The LC activities which take place on fuel farm area (0210, 0203, 0209) are so scheduled that they will be completed before the scheduled start times of their succeding PQC activities, leaving the required amount of time lag.

iii) Earth Work

The schedule of the critical earth work activities (0100, 0101, 0110) are left as they are, but noncritical ones are arranged in accordance with the related IC activities.

iv) Constructing Drainage Structures

A group of drainage activities, which can be finished before winter, are scheduled to start as early as possible, by fixing the completion of the last activity

of this group (O611) on the day before the first day of the winter holiday, and a total float of 2 days is left for them. This float value is appeared as 1 day on BKN schedule report (Appendix C.2.c), because BKN considers only working days in float computations.

The remaining part of drainage activities are scheduled to start after winter holiday by fixing the starting day of the activity 0630.

v) Laying Multi-cell Cable Passes under Shoulders.

out to be critical in the first PCS schedule report

(Appendix C.l.a): 0829, 0826, 0825, 0828, 0827, 0840, 0841

and 0842. On BKN schedule report (Appendix C.2.a.) only the

activity 0829 is critical, the others above, are nearly

critical having only 1 day total float. Therefore these

activities are scheduled to start at their computed starting

times. The schedules of subsequent activities of this chain are

determined by fixing the completion of 0800 which is the

last activity of the chain. If all preceding "multicell cable

passes" activities are to be started at their latest starting

times, there will be no interruption in this chain. But, there

is an opportunity to schedule some reasonable amount of float

for these activities.

vi) Shoulder Stabilization

Shoulder stabilization activities are the most time consuming ones among all the shoulder activities. Therefore, for these activities, work will be scheduled on 7 days of the week, excluding official holidays, while using PCS, in order

not to delay the project completion date given to the contractor. Since BKN program does not permit the specification of different work weeks for project activities, the work week, for this group of activities, will also be six days as the others. Consequently more shoulder stabilization activities will be on the critical path, and the project duration will come out to be longer in BKN reports.

In PCS schedule report (Appendix C.1.a) 0442 is the only critical shoulder stabilization activity. If the schedule of this activity is kept as it is, the computed project duration will not be affected. But the preceding shoulder stabilization activities cannot be completed until the start of 0442, if the "multi-cell cable passes" activities are to be executed in accordance with the schedule determined at the previous step. Because a shoulder stabilization activity cannot start before the completion of related multi-cell cable passes activity. Therefore, the start of the first activity of the shoulder stabilization chain (0403) is fixed on such a date that neither any interruption in the flow of multi-cell cable passes activities will be caused, nor any interruption in the flow of shoulder stabilization activities will occur. But, it is obvious that, in this case, the critical activity 0442 will be shifted, causing the extension of the project duration.

In BKN schedule report (Appendix C.2.a), the shoulder stabilization activities 0429, 0426, 0425, 0428, 0427, 0440, 0441 and 0442 have appeared as critical activities. Due to the same reason, these critical activities are shifted towards the project end. The extension caused in this case is more than the one observed in PCS reports, due to specification of

6-day work week.

vii) Laying PVC Pipes under Shoulders.

The total length of the chain of "laying PVC pipes under shoulders" activities is consiredably less than that of shoulder stabilization chain. Therefore the schedules of activities in this group is determined by fixing the completion of the last activity in the chain (0700) on a date which will occur, a time interval, equal to the duration of this activity, later than the completion of activity 0400. Then the activities are scheduled so that there will be no time lag between the activities of the chain.

viii) Forming Asphaltic Concrete Layer on Shoulders

The procedure, described in the above paragraph, is followed while scheduling this activity group, because the length of this chain is shorter than that of "laying PVC pipes under shoulders" chain. Therefore, the scheduling of "forming asphaltic concrete layer on shoulders" activities is started by fixing the completion of 0500 on the date which will occur a time interval, equal to the duration of activity 0500, later than the completion of the activity 0700.

ix) Top Soiling

The top soiling activities whose codes are 0906, 0914, 0913, 0912, 0905, 0900 and 0901 have appeared as critical, on reports obtained by both programs (Appendix C.1.b. and C.2.c). The computed completion time of activity 0901 is the project completion date since it is the last

activity of the critical chain. Therefore the schedules of these critical activities are left as they are, and the noncritical top soiling activities are so arranged that there will be no time gab between the activities of this chain.

The final schedule obtained is presented in Appendix F in a bar chart form.

CHAPTER VI

PROJECT CONTROL

A. NECESSITY FOR PROJECT CONTROL

One of the fundamental principles of management was stated by Henry Gantt: "The authority to issue an order involves the responsibility to see that it is executed" (15). Therefore when a manager has issued instructions that certain things are to be done, it is also his responsibility to provide a mechanism which will keep him continuously informed as to whether or not his orders are being carried out, so that he can decide on the corrective measures, if the progress is not satisfactory. It is obvious that no paper-plan will work continuously in practice, even if it is theoretically perfect. Unpredictable conditions and unknown factors may become effective at any time during the execution of the project causing delays and disturbing the smooth run of operations.

Based on the above discussion, the primary objective of project control may be formulated as: "to review the current situations in the light of previous experience and to forecast the future requirements, so that the work may be completed succesfully".

B. PROJECT CONTROL CYCLE

The control of a project must be dynamic and must respond immediately to changing conditions. Also, it is necessary to have a monitoring system, to measure the

differences between the planned and actual performances, which forms the basis of revising the original plan.

Measurement of actual achievements and comparison with the planned ones is, therefore, an essential feature of an effective control system.

The fundamental stages of project control cycle are: instruction, execution, measurement and correction by new instruction. The system used in a dynamic project control is shown diagrammatically in figure 42⁽³⁴⁾.

Constraints Preparation of Project Instructions Work Schedules Execution PLAN Project Objectives Measurement REPLAN Evaluation Feedbock Feedback of Performance Actual Performance against Schedules

Figure 42. Project control cycle

Physical and Operational

The functioning of project control cycle may be illustrated as:

- i) An original plan is formulated to meet the project objectives under the influence of existing physical and operational constraints.
 - ii) The plan is put into the form of job schedules.
- iii) Instructions are issued in accordance with these schedules.
- iv) The execution of instructions results in the accomplishement of a certain part of the project.

v) The actual performance on the project is measured at regular intervals whose frequency is influenced by following factors: the degree of uncertainty, the magnitude of the project, the time to completion and the troubles encountered. But, in general, two-weekly periods are accepted to be sufficient for contractors where monthly periods for owners.

Information for periodic reviewing of site operations is collected by activity status reports. A simple form of such a report (20) is given in figure 43.a, and the one used by TÜBİTAK (Turkish Scientific and Technological Research Center) in the control of Keban Dam Project is presented in figure 43.b.

		Report	k on Ac	etivity.	Status				
Works Section: Date:									
Reported by:									
Activity Code	Activity Descript.	Started Not Started Finished	Scheduled Start Date	Scheduled Start Date	Status (%)	Expected or Actual Finish Date	Reasons for Delay, If any		
		<u> </u>	(a)	<u></u>	<u> </u>			

	•	activity St	:	-t Period Start:_ Period End:_	
Activity Code	Activity Description	In This Period Start Date Finish Date (If Started) (If Finished)		% Completed In This Period	Expected Completion Date

Figure 43. Activitiy status reports

The accuracy and reliability of the data collected at this stage are of extreme importance. Because all the decisions that are to be made for corrective actions will be founded on these data.

- vi) The results of this measurement are fed back for comparison against original work schedules.
- vii) If the job is found to be delaying the remedial measures are to be determined in a very short time.

 Consequently, the network, with its schedules and bar charts, should be revised appropriately in order to have a new plan for the uncompleted part of the project.

The usual causes of time delay in construction works include:

- incorrect estimates of activity durations,
- unforeseen weather conditions,
- unpredictable delays in delivery of materials,
- strikes or other labor troubles,
- unexpected subsoil conditions,
- extras or deductions in work quantities.

When the project is behind the schedule, the network diagram may be revised and appropriate future activities may be shifted, or compressed by employing additional resources. The tendency to concentrate on critical activities in periodic reviews of work progress may be explained by the general rule that only by the compression of these activities, the delay can be compensated. But some noncritical activities may become critical if the compression is carried too far.

This fact should never be overlooked. Therefore the activities which are nearly critical should be taken into account while determining corrective measures. Then the costs of all possible corrective measures are to be forecast so that the alternative proposals can be compared with one another, to determine the optimum overall solution. In some cases the delayed completion date may come out to be a more economical solution.

Replanning phase of the cycle can only take place after the processes of execution, measurement, feedback and re-evaluation. Therefore effectiveness of control mechanism is dependent upon the speed and accuracy with which the feedback data is collected, transmitted and analysed. The continuous cycling of information, specially in large projects, involves considerable amount of repetetive analysis of the network. This process may consume so long time that control mechanism becomes ineffective. In such cases, the use of computers enables a greater speed of feedback and analysis, and therefore, more frequent cycling of control information than is manually possible.

CHAPTER VII

CONCLUSION

As the result of the previous chapters, it can be concluded that the planning of construction works is a must from both economical and juridical viewpoints. The degree of effectiveness in planning depends on many factors. If a contractor or owner want to enjoy the benefits of planning, attention must be paid to following points:

a. Organization

A capable organization is the first and the most important condition, which must be fulfilled for effective planning. A firm's organization is the arrangement of its interdependent parts, each of which has a function of its own and a relationship to the whole.

Authority and duty of each interdependent part of the organization should be clearly defined with its responsibility. This point is of extreme importance especially from the planning unit's angle. Because some managers still have the impression that the planners like to hold the authority but to reject the responsibility. The function of planning unit is to evauate the facts and forecasts and then to propose alternative ways of action, each being associated with probable benefits and shortcomings. In other words the planning unit prepares the basis of decision for the manager. It is the project manager who has the authority to select any of the proposed alternatives or any other solution.

Therefore, he himself, carries the responsibility of the decision made.

The functional chart of a construction organization is given in figure 44 in a compact form (19).

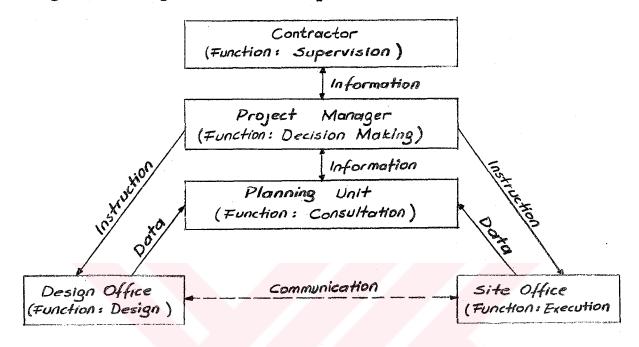

Figure 44. Functional chart for a construction organization.

b. Information Flow

The rapid flow of information within an organization is an important factor which increases the efficiency of management and thus the organization. Because if the project manager gets informed about the prevailing conditions as they arise, his decisions will be more accurate. Also, the necessary measures for the probable problems can be taken before they occur; and errors or inaccuries in the original plan can be corrected in a short time. Therefore, it may be stated that information is the blood of an organization and only by its regular flow the organization can be kept alive.

c. Data

It is evident that plans become more realistic, if duration and cost estimates of the project activities and even the establishment of relationships between them are based on reliable data.

Data collection in construction industry is more difficult than in any other sector, because it has some special features that are not encountered in others. Among these the wide range of operations and processes, and continuously changing conditions are the most important ones. For instance, construction of buildings, bridges, highways, airports, pipelines, dams tunnels etc. are all included in construction industry, although each of them requires different construction methods, equipments and labor skills. Since all construction firms are, more or less, specialized on a certain type of work, each firm should keep his own records of past experience, continuously and systematically. On these records activities and working conditions should be clearly indicated as well as the capacity used, duration and cost of activities.

The systematic handling of data and the working out of characteristic figures require the establishment of data banks which will help the planners in obtaining data for each type of work that they are not familiar with.

d. Planning Method

The advantages and disadvantages of three groups of planning methods are analyzed in Chapter III. Under the light of the discussions made in that chapter, it can be concluded

that network based methods have, in general, less shortcomings than bar charts and cyclogrammes, but they offer more advantages. Although bar charts and cyclogrammes can be used efficiently within the limited fields indicated in Chapter III, network based techniques are applicable to any type of work.

Network based planning methods should be considered in two categories: probabilistic and deterministic methods. Since construction costs and performance times can be estimated with sufficient accuracy, employment of deterministic techniques are more appropriate. In cases where some uncertainties are involved in time (and cost) estimates, there arises a tendency to use a probabilistic approach, like PERT. But it should be remembered that PERT is based on various assumptions; many of which are easily questionable. These assumptions may be considered on two separate levels:

i) Activities

PERT handles uncertainty by assuming that the probable durations of an activity are betä-distributed. The three time estimates (see Chapter IV) are then used to determine the end points (t_a and t_b) and the mode of this distribution (t_m), although these three points do not define a unique beta distribution. The expected mean time (t_e) and standard deviation (t_e) are determined by the following assumptions:

$$t_a + 4t_m + t_b$$

$$t_e = \frac{1}{6} (t_b - t_a)$$

Possible errors introducted to overall PERT computations, due to the assumptions above, are computed as (35):

- Worst absolute errors due to the assumption of beta-distribution only

in the mean time : 25 - 33%

in the standard deviation: 17%

- Worst absolute errors due to standard deviation assumption and the approximation of the mean time only

in the mean time : 33%

in the standard deviation: 17%

The are also some errors due to the inaccuracy of optimistic, pessimistic and most likely time estimates, even if the above assumptions hold correct.

ii) Network

Significant errors may be introduced into the calculation of expected network mean time (project duration) and standard deviation, even if the mean time, standard deviation and beta distribution of individual activities are correct. In the case studies carried out by K.R.MacCrimmon and C.A.,Ryvavec (35), the errors in the PERT- calculated mean time and standard deviation were found to be 10-30 per cent.

If there is only one path through a network that is significantly longer than any other path, then the PERT procedure for calculating the project mean time and standard deviation will give approximately correct results, since individual beta-distributions will sum up to an approximate

normal distribution. However, if there are a large number of parallel paths having approximately the same length, errors will be introduced in the PERT-calculated project mean and standard deviation.

Considering the brief explanation above together with the fact that PERT requires extra computational effort and hence additional cost, it can be concluded that deterministic planning methods are more suitable for construction management.

d. Use of Computer

The mathematical structures of network based methods make them suitable for computer processing. The use of computers in planning process increases the speed of information flow, and thereby provides a chance to managers to make quick decisions in periodically exact times. The speed of computer is also invaluable in project control phase.

The advantages of computer use should be considered together with some other factors making the manual computations preferable. First of all, computer processing is not available yet to all potential users. For instance, there are 110 computer centers in Turkey (36), and among these 41 centers are available for hiring machine time; but only 21 of them (2 in Adana, 7 in Ankara, 9 in İstanbul, and 3 in İzmir) are suitable for the processing of the available programs PCS and BKN. As pointed out before, the special BKN programs are in ALGOL language, but there is no computer system processing in ALGOL in Turkey.

The planner should select the most suitable program among the available ones. The detailed descriptions (Appendix B) and the comparison of PCS and BKN (Chapter V) are given in this study to englighten the potential users. The following figures may also help them in making the selection:

The computer (IBM 360-40) time needed to produce a schedule report and a bar chart out of the network model of Yeşilköy Airfield Infrastructure Project, which consists of 305 activities and 754 relationships, is 17 minutes by BKN and 22 minutes by PCS. The number of input cards needed for producing the same reports were 1384 and 911 for BKN and PCS respectively.

APPENDIX A

THE ACTIVITY LIST

OF
YEŞİLKÖY AIRFIELD INFRASTRUCTURE PROJECT

Code	Description	Duration	(days)
		PCS	BKN
0001	Project Start	0.0	0
	1. EARTH WORK		
	a. Earth Moving		
0100	On the Area to be Paved in North		
	and East	9.0	9
0101	Outside the Area to be Paved in		
	North and East	21.0	21
0102	On the Fuel Farm Area	7.0	7
	b. Borrowing and Filling the		
	Selected Material		
0110	Outside the Fuel Farm Area	20.0	20
0111	On the Fuel Farm Area	6.0	6
	2. LEAN CONCRETING		
0201	From PTW No.1 (24+60) to end of		
,	Link No.6	13.5	14
0203	PTW No.2 (Fuel Farm Area)	1.4	2
0205	Link No.10	5.0	5
0206	Link No.11	4.1	4
0207	FTO No.4	6.5	7
0208	FTO No.5	6.5	7
0209	PTW No.1 (Fuel Farm Area)	5.0	5
0210	Link No.7 (Fuel Farm Area)	5.0	5
	3. PAVEMENT QUALITY CONCRETING		
0300	Runway Strip No.6 (04+36 - 19+50)	6.3	6
0301	Runway Strip No.6 (19+50 - 34+36)	6.6	7

APPENDIX B

DESCRIPTIONS OF COMPUTER PROGRAMS

FOR

NETWORK COMPUTATIONS

1. PROJECT CONTROL SYSTEM (PCS)

The Project Control System (PCS) is designed to perform basic network computations discussed Chapter V and produce reports for a project whose network model has been established. PCS is prepared to process precedence networks which are difficult to analyze manually. However if the network is an arrow diagram, the system automatically converts it into a precedence diagram during generation and update runs.

The requirements, capabilities and special features of the system will be discussed under the titles "Preparation of Input", and "Output Reports".

PREPARATION OF INPUT

All input data must be submitted to PCS in form of card images. There are twelve different types of cards that may be submitted. These cards are divided into four general categories: activity (work item) property cards, network cards, output report cards and run cards.

a. Activity (Work Item) Property Cards

These cards are the input cards on which the user specifies:

- what activities are to be included in the network,
- the properties of each activity.

There are five different types of cards in this category: activity (work item) cards, milestone cards, progress reporting cards, schedule cards and resource cards.

i) Activity (Work Item) Cards

These cards are used to delete, change or add an activity to a network. Up to 5000 different activities can be contained within one network. The format of this type is:

Column 1. The identification code "G" must be entered.

Columns 2-5. The numeric network identification code.

Column 6. A valid activity modification code:

blank The activity represented by this card is to be added

- The fields on disk corresponding to those on this card are to be completely replaced
- D The activity represented by this card is to be deleted.

Columns 7-16. If the network is a precedence network, the activity identification code must be entered in cc 7-16. This code may be alphameric.

If the network is an arrow diagram, the code of tail event of the related activity must be entered in cc 7-10, columns 11-12 must be left blank, and the code of its head event must be entered in cc 13-16. These event codes may also be alphameric.

Columns 18-61. A description of activity may be entered.

Columns 63-66. The estimated duration of activity is
entered in the form of XXX.X where decimal point is implied.

Column 67. The starting day of the work week of activity may be entered:

blank or 1 Monday

- 2 Tuesday
- 3 Wednesday
- 4 Thursday
- 5 Friday
- 6 Saturday
- 7 Sunday

Column 68. The number of working days in a week is entered. If none is entered, the system assumes a five-day work week.

Column 69. The calender type to be associated with the activity may be entered. The valid codes are:

blank The holiday calender. No work will be scheduled for this activity on any holiday

- The special calender. No work will be scheduled for this activity on any holiday or special nonwork day.
- The standard calender. Work will be scheduled on all acceptable work week days (see Chapter V Part 3).

Column 70. The time unit, in which the duration of activity is expressed, is entered. The allowable time unit entries are:

blank Days

- 1 Hours
- 2 Half days

- 3 One-shift days
- 4 Two-shift days
- 5 Three-shift days
- 6 Weeks

Columns 71-80. A revised work item code may be entered.

ii) Milestone Cards

Milestone cards are used to specify network milestones. The user is allowed to identify up to 480 activities in his network as milestones. The card format is:

Column 1. The idendification code "L".

Column 2-5. The numeric network identification code.

Column 6. A valid modification code:

blank Add a new milestone to the network

- C Change the milestone description of a milestone already in the network
- D Delete the milestone from the network

Columns 7-16. Work item identification code is entered as explained for work item cards.

Column 18. The milestone position code:

The start of the work item is considered to be the milestone.

blank The end of the work item is considered to be the milestone.

Columns 20-63. The description of the milestone.

iii) Progress Reporting Cards are used to specify the actual start date, actual completion date, remaining duration, percent completed during this period or percent completed to date, actual cost of this period or actual

cost to date of individual activities in the network. The card format is:

Column 1. The identification code "J".

Columns 2-5. The numeric network identification code.

Column 6. Enter the letter C to specify that only the cost information is entered. Leave cc 6 blank to indicate that only time, or both time and cost information, are entered.

Columns 7-16. The activity identification code.

Columns 18-24. The actual start day of the work item is entered in the form DDMMMYY where:

DD - A two-digit number representing the day of the month

MMM- The first three letters of the month

YY - The last two digits of the year.

Columns 26-32. The actual completion date of the work item in the form DDMMMYY.

Columns 34-37. The remaining duration entered in time units with an implied decimal (XXX.X).

Column 39. The time unit conversion, which enables PCS to convert the value of remaining duration to "day-values", is entered as one of the following:

blank days

- l hours
- 2 half days
- 3 one-shift days
- 4 two-shift days
- 5 three-shift days
- 6 weeks

Columns 41-45. Percent completed this period entered with an implied decimal point (X.XXXX).

Columns 47-51. Percent completed to date entered with an implied decimal point (X.XXXX).

Columns 66-72. The actual cost of the reporting period is entered in whole dollars.

Columns 74-80. The actual cost to date is entered in whole dollars.

iv) Schedule (Fixed Date) Cards

The schedule card is optional input for either a network generation or an update run. The user may use schedule cards to specify, change, or delete the scheduled start date, scheduled completion date and organization codes of individual activities in the network. The format is:

Column 1. The identification code "I".

Columns 2-5. The numeric network identification code.

Column 6. The schedule card modification code:

- blank All fields on disk corresponding to those in the card are replaced.
 - C Only those fields that are punched replace their corresponding on disk.

Columns 7-16. The activity identification code.

Column 18. The type of scheduled start date desired for the activity. The number of the scheduled date type is the entry to be used.

- Type 1 These dates have no effect on the system
- Type 2 This represents the earliest date desired for PCS to schedule the start or the completion of the activity.

- Type 3 This represents the date desired for PCS to schedule the start or the completion of the activity, regardless of the early or late start or completion dates the system computes.
- Type 4 This fixes the late start or late completion of an activity.
- Type 5 This sets the late completion time of the activity equal to its computed early completion time.

Columns 20-26. The scheduled start date in the form DDMMMYY.

Column 28. The type of completion date desired for the activity. The valid entries are the same of those given for cc 18.

Columns 30-36. The scheduled completion date in the form DDMMMYY.

Columns 38-41, 43-46, 48-51, 53-56. These columns represent 4 different organization-code fields. These codes have no impact on network calculations, but can be used to provide selective output reporting.

v) Resource Cards

The resource card is used to relate up to 4 resources for any activity in the network as well as the estimated cost in whole dollars for the activity. The format used is:

Column 1. The identification code "K".

Columns 2-5. The numeric network identification code. Column 6. The modification code:

blank If any reseource information for this activity is entered for the first time

c To be used to change existing resource information on file.

Columns 7-16. The activity identification code

Columns 19-22, 29-32, 39-42, 49-52. A different resource

code that is to be associated with the activity may be
entered in each of these groups of columns.

Columns 23, 33, 43, 53. A resource code flag is entered: blank The units of resources used by this activity are to be considered a daily rate.

The units of resource used is a total, or constant value.

Columns 24-27, 34-37, 44-47, 54-57. The units of resource required is entered in the XXX.X form (decimal implied) if the related flag is blank and in XXXX form otherwise.

Columns 61-67. The total estimated cost of the activity in whole dollars.

b. Network Cards

The network cards are the input cards on which the user specifies data concerned with various properties of the network as a whole; that is relationships, time delays, calculation dates, calender, resources, and rescource descriptions.

Within the general category of network cards, there are five different types of cards: the network title card, preceding work item cards, calender cards, resource

description cards and resource grouping card.

i) Network Title Card

The network title card is used to identify the network and to specify the calculation dates for the network.

The format is:

Column 1. The identification code "B".

Columns 2-5. The numeric network identification code.

Column 6. This column must be left blank on a generation run. There must be a "C" for any other run type.

Columns 8-14. The project start (base) date is entered in the form DDMMMYY. This date should remain constant throughout the life of the network.

Columns 16-22. The data date which should not be earlier than the project base date is entered in the form DDMMMYY.

Columns 24-67. The network title.

Columns 69-75. The date of the computer run or any other desired date in DDMMMYY form.

Column 77. The user may enter a number in this column to indicate the sequence of run that may be made during the same day.

ii) Preceding Work Item Cards

Preceding work item cards are used to specify the relation-ships that exist between the various activities in the network, and to specify the time delay the user wants associated with each such relationship. These cards are not required for arrow diagrams. The card format of this type is:

Column 1. The identification code "H".

Columns 2-5. The numeric network identification code.

Column 6. The preceding activity modification code:

blank Add a relationship(s).

- c Change the type or value of the time delay that exists on disk for a particular relationship(s).
- D Delete an existing relationship(s) from the file.

Columns 7-16. The activity identification code.

Columns 18-27, 38-47, 58-67. The identification codes of preceding activities of the common activity are entered in these groups of columns.

Columns 29, 49, 69. The relationship the user wants established between the common activity and its predecessors are specified:

- S Start to start relationship
- F Completion to completion relationship
 blank Completion to start relationship

Columns 30, 50, 70. The type of time delay the user wants associated with the relationship specified in the preceding column is entered in cc 30, 50 or 70 -which ever is appropriate:

Enter "P" to indicate a time delay is expressed as percentage.

Enter blank, 1, 2, 3, 4, 5 or 6 -which ever identifies the applicable time unit- to indicate that the delay is expressed in this time unit (see Activity Cards)

Columns 32-36, 52-56, 72-76. The amount of time delay which is desired to be associated with the related

relationship is entered. For a percentage the format is X.XXXX, for time units the format is XXX.X, with the decimal point implied in both cases.

iii) Calender Cards

Calender cards are used to specify days, that are to be deleted from or restored to, the special nonwork day and/or the holiday calender associated with the network.

The format of this type is:

Column 1. The identification code "C".

Columns 2-5. The numeric network identification code.

Column 6. The calender card modification code:

blank Any calender dates appearing in cc 10-80 are to be added to the set of either

holidays or special nonwork days

Any calender date appearing in cc 10-80 are to be removed from the set of either holidays or special nonwork days.

Column 8. The two possible entries are:

- Indicates that the dates in cc 10-80 relate to the set of holidays
- Indicates that the dates in cc 10-80 relate to the set of special nonwork days.
- Columns 10-16, 18-24, 26-32, 34-40, 42-48, 50-56, 58-64, 66-72, 74-80. A day that is to be deleted from or restored to the calender specified in cc 8 may be entered in each of these groups of columns in the form DDMMMYY.

iv) Resource Description Cards

These cards are used to associate a code with and to provide a description of, the resources that are to be assigned to activities in the network, or to disassociate a code from a resource to which it was previously assigned. The format is:

Column 1. The idendification code "D".

Column 6. The resource description card modification code:

blank Add a resource code(s) and description(s)

D Delete the resource code(s) present in the card.

Columns 8-11, 30-33, 52-55. A different numeric resource code can be entered in each set of columns.

Columns 13-27, 35-49, 57-71. The descriptions of the resources whose codes are given in preceding columns.

v) Resource Grouping Cards

Resource grouping cards are used to add resources or delete them from resource groups. A maximum of 19 resource groups can be added to a network. The format of this type is:

Column 1. The identification code "E".

Column 6. A valid resource grouping card modification code:

blank Add a resource group to the network and/or add resources to a group.

D To delete an entire resource group (leave cc 30-33 blank) or to remove selected resources from a group (enter the resource codes into cc 30-78)

Columns 8-9. The numeric resource group code.

Columns 14-28. A description of the resource group.

Columns 30-33, 35-38, 40-43, 45-48, 50-53, 55-58,

60-63, 65-68, 70-73, 75-78. Resource codes, identifying resources the user wants to add or delete from this resource group.

c. Output Report Cards

The output report cards are the input cards on which the user specifies what output reports he wants the system to generate. There is only one type of output report card which is the "output request card".

i) Output Request Card

It is used to specify which output reports are wanted to be generated and to control the extend and scope of each such report. The card format of output request card is:

Column 1. The card identification code "F".

Columns 2-5. The network identification code.

Columns 11-17. Lower span date specifying the beginning date of the time period to be included in the report.

Columns 19-25. Upper span date specifying the ending date of the time period to be included in the report.

Columns 44-45. Resource Grouping Code. This field permits the user to restrict printing to work items using a resource belonging to a particular group code.

Columns 47-50. Resource Code. This field allows the user to restrict printing to:

- Activities using the resource specified, if no resource group code is specified in cc 44-45.
- Activities using this particular resource as well as activities using resources belonging to the resource grouping code specified in cc 44-45.

Column 52. If the user does not want work items having zero duration to be printed on reports specified on this card, he enters the letter "N" in cc 52, otherwise he leaves it blank.

Columns 53-80. Report Requests. There are two columns (in some cases only one) to specify a request for each type of report. A report is requested by punching a valid numeric code (N) into one of these columns. The valid numeric codes for each type of report are given in parentheses below. Punching the code (N) in an odd-numbered column will cause all dates to be printed as calender dates in the form DDMMMYY, where punching it in an even-numbered column will cause all dates to be printed as project days (number of days elapsed from the project start date) in the form XXX.X. The columns assigned and the valid numeric codes (N) for each report are:

- ec 53-54. Summary bar chart (4, 5, 6 or 7)
- cc 55-56 Milestone (3, 4, 5, 6, 7 or 8)
- cc 57-58 Work status card (any number)
- ce 59-60 Work status and progress report (1, 2, 3, 4, 5, 6, 7 or 8)
- cc 61-62 Schedule report (1, 2, 3, 4, 5, 6, 7 or 8)
- cc 63-64 Bar chart (1, 2, 3, 4, 5, 6, 7 or 8)

- cc 65-66 Resource assignment report (1, 2, 3, 4, 5, 6 or 7)
- cc 67-68 Resource utilization report (4, 5, 6 or 7)
- cc 69-70 Lump sum cost report (1, 2, 3, 4, 5, 6 or 7)
- cc 71 Monthly cost report (5 or 7)
- cc 73-74 Precedence report (any number)
- cc 75 Calender report (any number)
- cc 77 Master file (any number)
- cc 78 Back up master file (z)

The meanings of values that (N) can assume are:

- 1. Organization code 1 sequence
- 2. Organization code 2 sequence
- 3. Work item sequence
- 4. Early start sequence
- 5. Early finish sequence
- 6. Late start sequence
- 7. Late finish sequence
- 8. Start float sequence (see Chapter V Part 3)
- c. Run Card

The run card is the input card on which the user specifies the kind of run desired. There is only one type of run card:

i) Processing Control Card

This card is used to specify the type of run wanted and to indicate whether the network submitted is a precedence or an arrow diagram. The card format is:

Column 1. The identification code "A".

Columns 2-5. The network identification code.

Column 7. The type of run desired:

G - network generation run

U - update run

Z - maintenance run

R - output report run

Columns 9-11. This field is for the type of network in use:

blank A precedence diagram

CPM An arrow diagram

Columns 13-14. If the user wants the contents of input deck to be printed out, he should leave these columns blank, otherwise he should punch "NO".

Column 20. This column is used to indicate to the program whether or not the results of a PCS run are to be stored into PCS Permanent Storage.

Columns 22-24. The number of hours in a day is entered in these columns in XX.X form, where decimal point is implied. If no value is entered, PCS assumes an 8.0 hours-day.

There are two other types of card which are used in submitting the input card deck:

i) Group Header Card

Column	Information
1 .	Card identification code (B,C,D,E,F,G,H,I,
	J,K or L)
2-5	Must be blank
6	An asterisk (x)
7-80	Must be blank

OUTPUT REPORTS

I. Reports Used in Yeşilköy Airfield Infrastructure
Project

PCS can produce 14 different reports, only four of them which were used in planning the Yeşilköy Project will be described here:

a. Schedule Report

The schedule report gives the following information for each activity (see Appendices C.la and C.l.b):

- i) Description. This is the work item identification code and description as it appeared on the work item card (see "Activity Card").
- ii) Total duration. The total duration (XXX.X) is the duration converted into tenths of a day which appeared on work item card (see "Activity Cards").
- iii) Calender indicators. They are printed under the column marked with "CAL".

First indicator - number of days in the work week

Second indicator - start day of work week

Third indicator - calender used:

blank: No work on holidays

- No work on both holidays and special nonwork days.
- Work on all holidays and special nonwork days.

Fourth indicator- time unit in which the duration was specified on the work item card (see "Activity Cards").

- iv) Early and late start and completion dates. These dates are printed as either calender dates or project day as indicated in the request.
- v) Start float and finish float. The floats are printed in tenths of days (see Chapter V-Part 3).

b. Precedence Report:

The precedence report gives the following information for all work items in the network (see Appendix C l.e)

- i) Description of the work item.
- ii) Preceding work item. All of an activity's predecessors are given by their activity codes.
- iii) Relationship between activity and its predecessors.

 A code under the column "R" indicates the relationship:

blank End to start

S Start to start

F End to end

- iv) Time delay is printed under the column marked with "LAG VALUE". If this value is a percentage (P) is printed in the column "F". Otherwise the value is printed in tenths of days.
- v) Preceding work item start date is printed in the column "PWI START DATE". This is the early start date of the preceding activity.
- vi) Elapsed time. This is the length of time between the start and finish of the activity, reported in tenths of days.
- vii) PWI finish date. The late completion date of PWI is printed.

viii) Float. This is the PWI start float in tenths of days.

c. Calender Report

Calender report gives the calender which PCS uses in calculating the network (see Appendix C.l.c) using the following format:

Both the project day number and the calender date are printed.

Holidays are indicated by printing H to the left of the day number. Special nonwork days are indicated by printing NW to the right of the day number. A day that is both a holiday and a special nonwork day will have on H to the left and an NW to the right.

d. Bar Chart

The bar chart indicates the days on which actual work is scheduled to be performed on selected work items (see Appendix C.l.d).

The beginning date (Monday) of every work week within the span of the report is printed across the top of the page. Alloted to each week are seven columns (Monday through Sunday) the first of which is marked by (I) unless replaced by one of the bar chart report codes given below.

If the project day option is used, project day numbers where day number 1.0 is equivalent to project base date, appear across the top of the page. The report is divided in ten-day increments indicated by (I), unless replaced by one of the allowable report codes given below.

ii) End of File Card

Column	Information
1-5	Must be blank
6	An asterisk (x)
7-80	Must be blank

The various bar chart report codes are as follows:

- * Duration
- x Critical duration
- Start float
- N Negative start float

II. Other PCS Output Reports

a. Work Status and Progress Report

This report supplies the following information to the user of the system:

- i) The identification codes and the descriptions of activities; predecessors of these activities and their earliest start dates if the relationship is "start to start" or their lates completion dates if the relationship is either "end to start" or "end to end",
- ii) The original duration of the activity and the time unit in which the duration was specified,
- iii) The number of days in the work week of the activity,
- iv) If the execution of the activity is started, its remaining duration and completed percentage,
 - v) The expected start date of the activity,
- vi) The latest permissable completion date of the activity.

b. Resource Assignment Report

Resource assignment report lists the daily requirement of each activity using the specified resource (see "Output Request Card"), as well as total daily requirements. A separate resource assignment report may be printed for each selected resource.

This report is always printed for a period 7 weeks. The starting date for this period is governed by the lower span date (see "Output Request Card"). If

lower span date is not specified, project start date is taken as the starting date of the period.

c. Resource Utilization Report

This report gives the weekly requirements for a selected resource together with cumulative requirement from the project start date in a graphical form. If the working days option is used in requesting the report (see "Output Request Card") resource requirements are plotted for 10-day periods instead of weekly periods.

The system, itself, selects the scales to be used in preparing this report depending upon the highest periodic and cumulative amounts.

d. Lump Sum Cost Report

This report gives the estimated and actual cost of each activity as specified by the user. The activity's early start date, remaining duration, percent completed, late finish date and start float are also printed in the report. This report may be used for filing purposes.

e. Monthly Cost Report

Monthly cost report gives actual and estimated monthly expenditures for project activities, as well as the total monthly expenditure. Depending upon the user's request, the system may take either the early or the late finish of activities as basis in locating the expenditures in time.

f. Milestone Report

This report contains a list of network milestones, together with their scheduled dates and floats.

The other PCS output reports which are rarely used are:

- g. Summary Bar Chart
- h. Master File List gives all the input data for filing purposes.
- i. Backup Master File card images of master file to be used to free the disk for other uses between the network generation runs.
- j. Network Status Cards card images to be used as input for special ("user written installation") programs.

2. BAUKASTENNETZ (BKN)

The BKN system is developed by Prof.Georg Burkhart from the Institute of Construction Science in Technical University of Munchen between the years 1963-67 for analysis of activity-on-node networks. The system is composed of a main program which is described below in detail, and additional programs whose brief descriptions are given.

I. Main BKN Program

PREPARATION OF INPUT

The input data required by BKN primarily consists of data concerning:

- Individual activities that make up the network,
- The interrelationships between these activities.

This information is supplied to the system in form of card images only.

The input card types are:

1) Activity Description Cards

The user introduces the identification codes and the descriptions of activities by this type of cards in the following format:

Columns 2-10. The numeric activity identification code.
Columns 14-43. The description of the activity.

These cards should be sorted according to the sequence in which the activities are desired to appear on output reports.

ii) Relation Cards

By the use of these cards, the user supplies the information about the relationships existing between the project activities as well as the activity durations. A new card is required for each relationship. The number of relation cards submitted to the system must not exceed 4199, since this is the maximum number that BKN can process. The format of this card type is:

Columns 2-10. The numeric code of preceding activity
Columns12-20. The numeric code of the activity
Columns 27-30. The duration of the activity whose
code is punched in cc 12-20, in whole days.

Columns 35-38. The time delay between the activity and its predecessor in whole days.

Column 40. The type of relationship between the activity and its predecessor. The allowable entries to this field are

- O End to start with no time delay
- 1 End to start with some time delay
- 2 Start to start
- 3 A combination of start to start and end to end
- 4 End to end

iii) Calender Cards

This type of input cards are optional; when they are submitted, the output reports are prepared in terms of calender dates, otherwise the results of computations are printed out in working days.

Calender cards are used to specify the days on which the user wants work to be scheduled. The format of this type is:

Columns 1-2. The number representing the month of the year.

Columns 4-5. The last two digits of the year Columns 7-8, 10-11, 13-14, 16-17, 19-20, 22-23, 25-26, 28-29, 31-32, 34-35, 37-38, 40-41, 43-44, 46-47, 49-50, 52-53, 55-56, 58-59, 61-62, 64-65, 67-68, 70-71, 73-74, 76-77. The numbers representing the days of the month specified in cc 1-2, on which work will be scheduled.

Columns 79-80. A number indicating the sequence of the card within the calender card deck.

Calender cards should be submitted to the system in chronological sequence, and the number of working days should not exceed 1399 days.

iv) Exogene (Fixed) Date Cards

This type of cards in BKN corresponds to "schedule cards" of PCS and they are used to fix either the start or the completion of an activity on a desired date. The position of such a card within the input card deck indicates whether it shows a fixed start or a fixed end. The format is:

Columns 2-10. The numeric activity identification code.

Columns 17-20. The exogene date assigned to the activity whose code is entered in cc 2-10, in terms of working days elapsed from the project start.

v) Scaling Cards

Scaling cards are used to specify the number of working days to be plotted per 100 printing positions for bar chart. The format is:

Column 10. The entry to this field is 0

Columns 18-20. The number of working days to be plotted for each 100 printing positions.

There are some other card types which are optionally used:

- i) If the user punches -3 in cc 9-10 of a card, cc 14-63 of this card may be used in introducing some title.
- ii) A -2 in cc 9-10 causes a line to be left blank in print outs.
- iii) A -1 in cc 9-10 causes a page to be left blank in computer print outs in relation to the place of this card in the input deck.

INPUT CARD DECK

OUTPUT REPORTS

a. Schedule Report

The schedule report gives the following information for activities contained in the network (see Appendices C.2.a and C.2.c)

- The numeric identification code and the description of an activity is printed in columns "JOB-J" and "JOB-DESCRIPTION" respectively.
- The precedessors of the activity are given under the title "JOB-I".
- The type of relationships specified between the activities and their predecessors are given in column "TYP" and the related time delay in column "T.D." in whole days.
- The duration of activities are printed in whole days under "D-J" column.
- Then the earliest start, earliest end, latest start and latest end times for all activities (J) are printed under related columns either in terms of calender dates or working days.
- The computed total and free float values for each activity (J) are given under columns named "GF-J" and "FF-J" respectively.

The order of appearance of activities in schedule report is identical to their sequence within the first deck of activity description cards.

If the user submits a deck of calender cards the system prints out the schedule report in terms of calender

dates, otherwise in working days.

b. Bar Chart

BKN gives the results of network computations in form of a bar chart also (see Appendix C.2.f). The bar chart of BKN provides the user with information about activity code, description and duration beside which activity's duration is plotted, according to the scale specified in scaling card, from its early start to its early end. The earliest start and earliest end times are printed in terms of calender dates or working days. The sequence of activities in bar chart is identical to the second deck of activity description cards.

c. Calender Report

The calender report gives the calender which is used by BKN in network computations as given in Appendix C.2.e.

d. Critical Path Report

This report (see Appendices c.2.b and c.2.d) lists the identification codes of critical activities. Special remarks are made for neutral and negative critical activities.

II. Additional BKN Programs

a. BKN-BAR

This program supplies a bar chart which is printed according to early positions of activities. The start and end points of bars are marked with starting and completion dates of the related activities.

The user is permitted to specify the spacing between the bars and the time scale.

b. BKN-BLOCK

In some cases, there may be definite periods within the project duration in which certain project activities cannot be carried out. This causes difficulty in the preparation of work schedules. BKN-BLOCK is designed to solve this problem taking such activities, which are specified in input, into account in preparing the job schedule.

Activities which cannot be carried out in those periods are divided into three groups in accordance with their nature:

- i) arbitrarily divisible (intermittent) activities which can proceed piecewise at irregular periods of time,
- ii) indivisible (continuous) activities which have to be worked without interruption until finished,
 - iii) limitedly divisable activities.

The program schedules the first group of activities such that the execution is stopped when blockade is reached, then re-started after the blockade.

The second group of activities are scheduled to start after blockade when any part of the them fall into blockade.

When a part of an activity of the third group falls into blockade; if the duration of this part is smaller than a specified minimum value, activity will be compressed, if the duration of the part outside the

blockade is smaller than the given minimum amount, the activity is treated like an indivisible one. Beside the two cases above an activity is scheduled like a divisible activity.

c. BKN-CUT

This program is very helpful when some activities come out to have negative total float values due to fixed dates. If the user gives a list of activities on the negative total float path showing their priority in compression process, BKN-CUT performs the necessary compressions until negative total floats are eliminated. If the compression of activities in the list does not suffice, it prints "local critical path" showing the activities to be further shortened.

d. BKN-PERM

This program is used to find out, by permutations, the operational sequencing of activities according to given priorities after the causal network is established. The computer prints the result of each permutation and enables the decision maker to select the most suitable one.

e. BKN-CONTROL

BKN-CONTROL program produces a job schedule report and a bar chart which show the projection of work status at the control date according to the fixed project end date. The program requires input containing control time, completed activities, the time needed for the completion of activities which are started, but not completed yet, and expected future changes in the network together with the data of the original network.

f. BKN-MOD

This special program is used with disc to restore the whole network as a result of network modifications and control computations. Following changes in the structure of a network may be done by this program:

- i) deleting activities from the network,
- ii) deleting relationships from the network,
- iii) changing durations of activities,
- iv) changing type of relationship and/or associated time delay,
 - v) adding activities to the network,
 - vi) adding relationships to the network.

g. BKN-POT .

BKN-POT is used to determine resource requirements according to early start of activities. Upto 11 different resource groups can be specified. This program requires voluminous input data for each resource group to compute the necessary amount required in function of each activity. In case of excavation equipment, for example, available types of equipment with their capacity (volume, HP, etc.) and weight must be provided for the related activity and the volume of work or transportation distance (km). The output report gives the total capacity required (volume, HP, etc.) for each activity. It also gives, in separate lists, the capacity of each equipment together with the time period (from to) in which it is needed. At the end of group lists "maximum capacity" and the value of resource area (capacity x duration) are printed for resource leveling purposes.

h. BKN-COST

There are two special BKN programmes to be used to handle the cost aspect of a project.

- i) Cost Planning This program produces a report of cumulative costs in a tabular form which is based on the early start of activities. This report can be prepared according to working days at project start, or monthly, from any project control date to end date of the project. The program requires the activity costs in addition to input data related to network.
- ii) Payment Plan If the planner specifies the amount of contractor's receipt upto the control date, the second program computes the monthly payments to be made from this date on. This program produces another report indicating the cost overrun and underrun together with their causes for each project activity. The data needed for this purpose are composed of:
 - total receipts of the contractor,
- finished quantity, contractor's claim on finished quantity, remained quantity and contractor's claim on remained quantity for each project activity,
- changes in activity volume of work and its unit price.

APPENDIX D

GLOSSARY

Borrow and Fill of the Selected Material - Seçme Malzeme Ariyet ve Dolgusu

Drainage - Drenaj

Earth Moving - Toprak İşleri

FTO (Fast Turn-off) - Sürat Geçidi

L.C. (Lean Concrete) - Zayıf Temel Betonu

Lay. Top Soil - Nebati Toprak Serilmesi

Link - Bağlantı

Mult.Cab.Pas.(Multi-cell Cable Passes) - Çok delikli Kablo geçitleri

P.Q.C. (Pavement Quality Concrete) - Kaplama Beton

Project End - Proje Bitimi

Project Start - Proje Başlangıcı

PTW (Parallel Taxiway) - Paralel Servis Yolu

PVC Cab.P. (PVC Cable Pipes) - PVC Kablo Boruları

Runway - Pist

Sh.Asp.C. (Forming Asphaltic Concrete Layer on Shoulders)

- Banketlerin Beton-Asfaltla Kaplanması

Sh.St.(Shoulder Stabilization)- Banket Stabilizasyonu

Zone - Bölge
