

TEZ ŞABLONU ONAY FORMU
THESIS TEMPLATE CONFIRMATION FORM

1. Şablonda verilen yerleşim ve boşluklar değiştirilmemelidir.
2. **Jüri tarihi** Başlık Sayfası, İmza Sayfası, Abstract ve Öz'de ilgili yerlere yazılmalıdır.
3. İmza sayfasında jüri üyelerinin unvanları doğru olarak yazılmalıdır. Tüm imzalar **mavi pilot kalemle** atılmalıdır.
4. **Disiplinlerarası** programlarda görevlendirilen öğretim üyeleri için jüri üyeleri kısmında tam zamanlı olarak çalıştıkları anabilim dalı başkanlığının ismi yazılmalıdır. Örneğin: bir öğretim üyesi Biyoteknoloji programında görev yapıyor ve biyoloji bölümünde tam zamanlı çalışıyorsa, İmza sayfasına biyoloji bölümü yazılmalıdır. İstisnai olarak, disiplinler arası program başkanı ve tez danışmanı için disiplinlerarası program adı yazılmalıdır.
5. Tezin **son sayfasının sayfa** numarası Abstract ve Öz'de ilgili yerlere yazılmalıdır.
6. Bütün chapterlar, referanslar, ekler ve CV sağ sayfada başlamalıdır. Bunun için **kesmeler** kullanılmıştır. **Kesmelerin kayması** fazladan boş sayfaların oluşmasına sebep olabilir. Bu gibi durumlarda paragraf (¶) işaretine tıklayarak kesmeleri görünür hale getirin ve yerlerini **kontrol edin**.
7. Figürler ve tablolar kenar boşluklarına taşmamalıdır.
8. Şablonda yorum olarak eklenen uyarılar dikkatle okunmalı ve uygulanmalıdır.
9. Tez yazdırılmadan önce PDF olarak kaydedilmelidir. Şablonda yorum olarak eklenen uyarılar PDF dokümanında yer almamalıdır.
10. Tez taslaklarının kontrol işlemleri tamamlandığında, bu durum öğrencilere METU uzantılı öğrenci e-posta adresleri aracılığıyla duyurulacaktır.
11. Tez yazım süreci ile ilgili herhangi bir sıkıntı yaşarsanız, [Sıkça Sorulan Sorular \(SSS\)](#) sayfamızı ziyaret ederek yaşadığınız sıkıntıyla ilgili bir çözüm bulabilirsiniz.
1. Do not change the spacing and placement in the template.
2. Write **defense date** to the related places given on Title page, Approval page, Abstract and Öz.
3. Write the titles of the examining committee members correctly on Approval Page. **Blue ink** must be used for all signatures.
4. For faculty members working in **interdisciplinary programs**, the name of the department that they work full-time should be written on the Approval page. For example, if a faculty member staffs in the biotechnology program and works full-time in the biology department, the department of biology should be written on the approval page. Exceptionally, for the interdisciplinary program chair and your thesis supervisor, the interdisciplinary program name should be written.
5. Write **the page number of the last page** in the related places given on Abstract and Öz pages.
6. All chapters, references, appendices and CV must be started on the right page. **Section Breaks** were used for this. **Change in the placement** of section breaks can result in extra blank pages. In such cases, make the section breaks visible by clicking paragraph (¶) mark and **check their position**.
7. All figures and tables must be given inside the page. Nothing must appear in the margins.
8. All the warnings given on the comments section through the thesis template must be read and applied.
9. Save your thesis as pdf and Disable all the comments before taking the printout.
10. This will be announced to the students via their METU students e-mail addresses when the control of the thesis drafts has been completed.
11. If you have any problems with the thesis writing process, you may visit our [Frequently Asked Questions \(FAQ\)](#) page and find a solution to your problem.

Yukarıda bulunan tüm maddeleri okudum, anladım ve kabul ediyorum. / I have read, understand and accept all of the items above.

AN ALTERNATIVE WAY FOR REDUCTION OF SALMONELLA IN
POULTRY PRODUCTS: BACTERIOPHAGES

A THESIS SUBMITTED TO
THE GRADUATE SCHOOL OF NATURAL AND APPLIED SCIENCES
OF
MIDDLE EAST TECHNICAL UNIVERSITY

BY

MUSTAFA GÜZEL

IN PARTIAL FULFILLMENT OF THE REQUIREMENTS
FOR
THE DEGREE OF DOCTOR OF PHILOSOPHY
IN
BIOTECHNOLOGY

JUNE 2022

Approval of the thesis:

**AN ALTERNATIVE WAY FOR REDUCTION OF SALMONELLA IN
POULTRY PRODUCTS: BACTERIOPHAGES**

submitted by **MUSTAFA GÜZEL** in partial fulfillment of the requirements for the degree of **Doctor of Philosophy in Biotechnology, Middle East Technical University** by,

Prof. Dr. Halil Kalıpçılar
Dean, Graduate School of **Natural and Applied Sciences**

Assoc. Prof. Dr. Yeşim Soyer
Head of the Department, **Biotechnology**

Assoc. Prof. Dr. Yeşim Soyer
Supervisor, **Biotechnology, METU**

Prof. Dr. Mustafa Akçelik
Co-Supervisor, **Biology, Ankara University**

Examining Committee Members:

Prof. Dr. Candan Gürakan Gültekin
Food Engineering, METU

Assoc. Prof. Dr. Yeşim Soyer
Supervisor, Biotechnology, METU

Prof. Dr. Zeliha Yıldırım
Food Engineering, Niğde Ömer Halisdemir University

Prof. Dr. Bülent Kabak
Food Engineering, Hitit University

Assoc. Prof. Dr. Halil Mecit Öztop
Food Engineering, METU

Date: 03.06.2022

I hereby declare that all information in this document has been obtained and presented in accordance with academic rules and ethical conduct. I also declare that, as required by these rules and conduct, I have fully cited and referenced all material and results that are not original to this work.

ABSTRACT

AN ALTERNATIVE WAY FOR REDUCTION OF SALMONELLA IN POULTRY PRODUCTS: BACTERIOPHAGES

Güzel, Mustafa

Doctor of Philosophy, Biotechnology
Supervisor: Assoc. Prof. Dr. Yeşim Soyer
Co-Supervisor: Prof. Dr. Mustafa Akçelik

June 2022, 234 pages

Antibiotic resistance of pathogenic microorganisms is a severe public health problem. One of the main reasons of the resistance is the overuse of antibiotics in veterinary and food animals. Non-typhoidal *Salmonella* is a major foodborne pathogen that causes millions of cases each year, worldwide. Although *Salmonella* causes outbreaks in almost all food commodities, it is mostly associated with poultry. In addition to high prevalence in poultry, *Salmonella* isolates recovered from poultry have shown multi drug resistance. Use of bacteriophages (phages) has been emerged as a viable alternative for biocontrol of *Salmonella*. Phages are bacterial viruses that have narrow host range, and are unable to infect eukaryotic cells. They could be utilized for different applications from medicine to food safety. In this study, the main purpose was to isolate and characterize bacteriophages that can be used against multidrug resistant *Salmonella* serotypes in cattle and poultry farms. 57 samples were collected from poultry farms, cattle farms, and wastewater facility, in 11-month span. From the samples, 12 *Salmonella* and 68 phages were isolated. Antibiotic resistance profiles of *Salmonella* isolates were characterized. 66% of *Salmonella*

isolates were multidrug resistant. Genomic clustering and serotypes were determined by pulsed field gel electrophoresis (PFGE). Most abundant phages were Enteritidis phages. Isolated phages purified and stored. Lytic profiles of phages against various hosts were determined. Most of the phages showed broad host range. Based on the host range most potent phages were determined, and phenotypic (host-range, one-step growth, latent period, burst size, adsorption rate, transmission electron microscopy (TEM)) and genomic (PFGE, genome sequencing) features were characterized. Dynamic interaction between phages and hosts were investigated with bacterial reduction curves and virulence index. Enteritidis phages inhibited bacterial growth even at low concentrations. Effectiveness of several phages were tested against their hosts in *in vitro* feed model. Enteritidis phage significantly reduced host population in feed. In conclusion, a fundamental basis was prepared for a potential phage product.

Keywords: *Salmonella*, Bacteriophage, Genomics, Food Safety

ÖZ

KANATLI ÇİFTLİKLERİNDE SALMONELLANIN AZALTILMASI İÇİN ALTERNATİF BİR YOL: BAKTERİYOFAJLAR

Güzel, Mustafa
Doktora, Biyoteknoloji

Haziran 2022, 234 sayfa

Patojenik mikroorganizmaların antibiyotik direnci çok ciddi bir halk sağlığı sorunudur. Gelişen direncin temel sebeplerinden biri antibiyotiklerin veteriner ve Çiftlik hayvanlarındaki aşırı kullanımudur. Tifo etmeni olmayan *Salmonella* her yıl milyonlarca vakaya sebep olan gıda kaynaklı bir patojendir. *Salmonella* hemen her türlü gıdada salgınlara yol açsa da temel olarak kanatlılarla ilişkilendirilir. Kanatlılardaki yüksek görünme oranına ek olarak kanatlılardan izole edilen *Salmonella* çoklu ilaç direnci göstermektedir. Bakteriyofajlar, kısaca fajlar, *Salmonella*'nın biyokontrolünde başarılı bir alternatif olarak ilgi görmektedir. Fajlar dar konakçı aralığına sahip bakteri virüsleridir ve ökaryotik hücreleri enfekte edemezler. Fajlar tıptan gıdaya kadar birçok farklı alanda değerlendirilebilir. Bu çalışmanın temel amacı büyükbaş ve kanatlı çiftliklerinde çoklu ilaç direnci gösteren *Salmonella* serotiplerine karşı etkili fajların izolasyonu ve karakterizasyonudur. 11 aylık bir dönemde, kanatlı çiftlikleri, büyükbaş çiftlikleri ve atık su tesisinden toplam 57 örnek toplanmıştır. Bu örneklerden 12 *Salmonella* ve 68 faj izole edilmiştir. *Salmonella* izolatlarının antibiyotik direnci profili karakterize edilmiştir. *Salmonella* izolatlarının %66'sı çoklu ilaç direnci göstermiştir. Genomik kümeler ve serotipler

vuruşlu alan jel elektroforezi (PFGE) ile analiz edilmiştir. Enteritidis fajları en sık karşılaşılan fajlar olmuştur. İzole edilen fajlar saflaştırılıp dondurulmuştur. Fajların farklı konakçılara karşı litik profilleri belirlenmiştir. Fajların çoğunluğu geniş konakçı aralığına sahiptir. Konakçı aralığı temel alınarak en etkili fajlar belirlenmiş ve fenotipik (tek adımlı büyüme eğrisi, latent periyodu, patlama büyüklüğü, adsorpsiyon oranı ve geçirimli elektron mikroskobu (TEM)) ile genomik (PFGE, tüm genom sekansları) özellikleri karakterize edilmiştir. Fajlar ve konakçıları arasındaki dinamik ilişki bakteriyel azalma eğrisi ve virülans endeks ile analiz edilmiştir. Enteritidis fajları, düşük konsantrasyonlarda bile bakteriyel büyümeyi engellemişlerdir. Çeşitli fajların yem ortamında konakçılarına karşı etkisi *in vitro* olarak test edilmiştir. Enteritidis fajı yem ortamında konakçı popülasyonunu önemli ölçüde azalttığı görülmüştür. Sonuç olarak, çalışmamızla birlikte potansiyel bir faj ürünü için gerekli olan temel altyapı sağlanmıştır.

Anahtar Kelimeler: *Salmonella*, Bakteriyo-faj, Genomik, Gıda Güvenliği

To my spouse and daughter

and

To my parents

ACKNOWLEDGEMENTS

First, I would love to express my deepest gratitude to my dear supervisor Assoc. Prof. Dr. Yeşim Soyer for her endless support and trust. I will forever be in her debt. I am proud to be her student, and will remain a part of her lab until she kicks me out.

I met with a lot of wonderful people during this long journey. I like to thank all the former and current FSL members. Throughout my journey, I always feel blessed to be a part of this lab. I would like to thank my dear friends, Aysu, Ayşe, Ayşenur, Diala, Emre, Irem, Hilal, Nisa, Şahin, Segah, as they tolerated me all the times.

I would love to thank my thesis committee members, Prof. Dr. Candan Gürakan Gültekin and Prof. Dr. A. Kadir Halkman for their guidance throughout my studies.

I am eternally grateful to Prof. Dr. Bülent Kabak and Prof. Dr. Savaş Bahceci, for their full support and encouragement.

I would like to thank Prof. Dr. Osman Yaşar Tel for his support, and invaluable help with the samples.

This work is partially funded by Scientific and Technological Research Council of Turkey under grant number TUBİTAK 119O345.

And above all, I would love to thank my family, for their unconditional love and support.

CHAPTER 1

INTRODUCTION

Foodborne diseases have been a global health problem. World Health Organization (WHO) estimated that 600 million people suffered from foodborne illnesses, and 420000 deaths were associated with foodborne diseases. Furthermore, most impacted group from deaths were the infants. Although children under 5 years old were represented 9% of the world population, 40% foodborne mortalities linked with children (Havelaar et al., 2015). Among the most prevalent causative agents, top 5 organisms were; Norovirus, *Escherichia coli*, *Campylobacter* spp., Non-Typhoidal *Salmonella* spp, (*Salmonella*), and *Shigella* spp.

As one the major foodborne pathogens, *Salmonella* causes both diarrheal and invasive diseases. *Salmonella* was associated with nearly 80 million cases, and 60000 deaths (Havelaar et al., 2015). In addition to health related issues, *Salmonella* related annual economic loss was estimated as 2.7 billion Dollars in the United States (US), and 3 billion Euros for the European Union (EU) (Mather et al., 2013).

The main source of *Salmonella* is the poultry, pork and egg products (Antunes et al., 2016). Indeed, highest number of *Salmonella*-positive samples were spotted in poultry samples. Furthermore, poultry meat were the most *Salmonella* outbreak associated food commodities in 2020 in the EU (EFSA & ECDC, 2021). However, all of the food commodities have been linked with *Salmonella* outbreaks worldwide.

Prevention of salmonellosis requires careful implementation of intervention strategies throughout food production chain, from farm to fork (Ehuwa et al., 2021). Pathogenic microorganisms that are already present in animal before slaughter might cause contamination. In addition, cross contamination might occur during processing from contaminated carcasses or surfaces (Milho et al., 2019). Therefore, intervention strategies should start pre-slaughter by both reducing the prevalence of *Salmonella*

contaminated flocks, and reducing the pathogen concentration in contaminated flocks (Pessoa et al., 2021). Moreover, interventions possess a critical importance in terms of elimination of this foodborne pathogen at every step of production.

A number of intervention strategies are readily used in poultry production from chemical decontaminants to physical treatments. However, each strategy has a downside. For example, chlorine based chemicals are not generally recognized as safe (GRAS), organic acids cause undesirable changes in organoleptic properties, and physical treatments (e.g. ionizing radiation, UV) have negative effect on texture and color (Han et al., 2022). Antibiotics have widely been used in farm animals in order to fight against *Salmonella*. However, misuse and overuse of these substances leads spreading of antibiotic resistant bacteria (WHO, 2021). More than 700000 mortality is associated with antibiotic resistance infections annually (El-Shibiny & El-Sahhar, 2017). In addition to health and sociological consequences, each year antibiotic resistant infections cause more than 200 million Dollars economic loss in the EU alone (OECD, 2016). Due to the downsides of conventional intervention methods, implementing new strategies to control *Salmonella* in foods and production facilities gained importance (Barroug et al., 2021).

Bacteriophages, phages, are the prokaryotic viruses. Phages, the most abundant entities on the planet, their number is 8 to 10 fold higher than bacteria (Dion et al., 2020). They are abundant in variety of environments and non-pathogenic to humans. Phages have two possible life cycles depending on their interactions with the target host; lysis and lysogeny. Lytic phages lyse the cell after an infection cycle. A phage that replicates only with lytic cycle is called virulent. On the other hand, phages undergo lysogeny are called temperate (Gao et al., 2020). Virulent phages have been emerged as viable biocontrol agents against pathogenic bacteria due to several advantages. First of all phages are natural and the most environmentally friendly intervention method available (Moye et al., 2018). There are commercial phage products on the market with generally regarded as safe (GRAS), Halal and Kosher certificates. Phages do not require additives or adjuvants; they often come with a low

level saline solution. Furthermore, cost of phage application is typically much less than most other intervention methods (Moye et al., 2018). On the other hand, phages are required to be well characterized phenotypically and genotypically before applications (Chan et al., 2013). Phages must satisfy a number of genomic and phenotypic features to avoid complications. Their interactions with their hosts must be fully uncovered before application (Żbikowska et al., 2020).

In this study, bacteriophages infecting *Salmonella* were isolated from cattle-poultry feces and wastewater in order to offer an alternative method to antibiotics since antibiotic resistance became an important concern. The samples were supplied from several locations in Turkey. Since the distribution of *Salmonella* serovars is different in distinct regions, bacteriophages isolated in Turkey have a significant importance because they can be effective against local *Salmonella* serovars prevalent in Turkey. Besides that, *Salmonella* isolation and their genomic characterization was performed to provide a better understanding of *Salmonella* strains in these samples.

Moreover, the efficacy of isolated bacteriophages was evaluated on various *Salmonella* strains and some of their characteristics were determined to identify them so that they can be employed as biocontrol agents to reduce the risk of *Salmonella* contamination in foods and food processing facilities. The identified bacteriophages will make a major contribution to the phage database.

The main purpose of this study was to isolate and characterize phages that effective against the most prevalent *Salmonella* serotypes in cattle and poultry farms. It was aimed to create a fundamental basis for a phage product that could be used feed additive and/or surface decontaminant in the short term, and to reduce the *Salmonella* population in poultry and cattle products in the long term. To reach these goals:

- Determination of *Salmonella* load and serotypes in poultry and cattle farms and sewage – *Salmonella* isolation and count in poultry farms and sewage was done and serotypes were determined via molecular identification

methods. Antimicrobial resistance of *Salmonella* isolates was also determined.

- Isolation and characterization of bacteriophages from poultry and cattle farms and sewage – Isolated bacteriophages characterized phenotypically and genotypically. Depending on the host range, most effective phages were whole genome sequenced.
- Reducing *Salmonella* load in feed– Bacteriophages were selected based on their target host, and were tested as potential feed additive.

CHAPTER 2

LITERATURE REVIEW

2.1 *Salmonella*

Salmonella is a Gram negative, rod shaped, facultative anaerobic bacteria. *Salmonella* cells are motile with peritrichous flagellae. *Salmonella* is able to grow between 5-46 °C and 3.8-9.5 pH range (Vandeplas, 2017). *Salmonella* has two species; *Salmonella bongori* and *Salmonella enterica*. *S. enterica* is mainly associated with warm-blooded animals, and has six subspecies. These subspecies are further divided into “serotypes” based on their flagellar and somatic antigen structures. Among those subspecies, *S. enterica* subsp. *enterica* (*Salmonella*) is the main zoonotic pathogen that causes diseases humans and animals (Chan et al., 2003). Currently, there are 1585 serotypes under *S. enterica* subsp. *enterica*, most of which were named after a geographical location. These locations are including but not limited to cities, countries, rivers, and lakes. Some earlier serotype names such as Enteritidis and Typhi were associated to clinical syndromes (Gossner et al., 2016). Some of the serotypes are host specific, such as *S. Gallinarum* and *S. Pullorum* are specific to poultry, and *S. Dublin* in cattle. On the other hand, some serotypes are not host specific, and may infect multiple species, including humans (Revolledo & Ferreira, 2012; Wigley, 2014).

As one of the most prevalent foodborne pathogens, *Salmonella* cause millions of cases worldwide (Hendriksen et al., 2011). Although *Salmonella* is abundant in environment major source of it is poultry. EFSA report confirms that most of the *Salmonella* cases in Europe is linked to zoonoses. In addition to humans, *Salmonella* impose a constant threat to farm animals. For example, *Salmonella* infection in cattle often result with diarrhea and fever. In uncommon cases, *Salmonella* infection resulted in death (Hoelzer et al., 2011). *Salmonella* infection in dairy herds are

associated with reduced milk production that resulted in increased production costs and antibiotic residue in milk. In asymptomatic cases, animals become carriers of *Salmonella* and might transmit the pathogen to humans (Cobbold et al., 2006). Antibiotics have been used in veterinary for the treatment of diseases (Landers et al., 2012).

Antibiotics inhibit or eliminate bacteria with five main mechanisms. These are, protein synthesis inhibition, nucleic acid synthesis disruption, metabolic pathway interference, and cell wall synthesis inhibition, and disruption of cell wall (Tenover, 2006). Different antibiotic classes affect the target with a different mechanism. For example, fluoroquinolones inhibit DNA synthesis, while cephalosporins inhibits cell wall synthesis. However, overuse of antibiotics in chicken farms to prevent pathogen contamination was linked to rapid increase in antibiotic resistant bacteria (Landers et al., 2012).

Antibiotic resistance is a natural phenomenon. Antibiotic resistance occurs when a drug is ineffective for the treatment of the given pathogen (Alcaine et al., 2007). It is caused by plasticity and adaptability of bacterial genome (McDermott et al., 2018). The resistance occurs with a number of mechanisms. For example, bacteria might alter the configuration or cleave the antibiotic with the enzymes such as β -lactamases, or modify the target of antibiotic such as mutations in DNA gyrase for quinolone resistance (Peterson & Kaur, 2018). Antibiotic resistance might be intrinsic, meaning that pathogen might be less susceptible innately to antibiotic class due to surface characteristics or genomic features (Tenover, 2006). However, a more serious public health threat is the acquired resistance. Acquired resistance is the acquisition of resistance factor (e.g. efflux pump) via horizontal gene transfer (HGT) (Baquero et al., 2009). HGT occurs via three mechanisms; transformation of free DNA from environment, conjugation by mobile genetic elements, and transduction by bacteriophages (Hu et al., 2017). Horizontal gene transfer enables the spread of resistance genes presented on mobile genetic elements such as plasmids and transposons. With horizontal gene transfer, resistance may spread globally in a very short span (Ochman et al., 2000). For example, colistin resistance, which previously

known to occur only through chromosomal mutations, has disseminated worldwide in 10 years through *mcr* gene family (Hussein et al., 2021). In addition, chromosomal genes might also be mobilized and disseminated by plasmids. For example, *ampC* gene, a chromosomal β -lactamase gene which confers cephalosporin resistance in *Enterobacteriaceae*, has been found on plasmids, and spread globally (Jacoby, 2009).

Starting with the early 90s, antimicrobial resistance has been observed in *Salmonella* (WHO, 2013). However, over and misuse in medicine and veterinary practices, as well as using antibiotics as growth promoters in food animals accelerated the spread of antibiotic resistance greatly (CDC, 2013). Antimicrobial resistance is one of the most severe health problems. Ineffective antibiotics leads longer treatment durations, and even life threatening situations in surgeries, cancer treatment, and organ transplants and dialysis. EU parliament banned the growth promoter of antibiotic in 2006, and banned prophylactic use of antibiotics by 2022 (Patel et al., 2020).

Fluoroquinolones, third generation cephalosporins, and azithromycin are clinically important antibiotics for the treatment of *Salmonella*. Moreover, carbapenems are used as last resort antibiotics as most *Salmonella* strains are susceptible to carbapenems. Therefore, emerging resistance against these antibiotics are considered as a serious public health issue (WHO, 2017). Antibiotic resistance of *Salmonella* from various sources have been monitored in different parts of the World for over 20 years. For example, in the US, antimicrobial resistance data is collected and published by National Antimicrobial Resistance Monitoring System (NARMS). The results are available publicly in an interactive interface (Karp et al., 2017). In general resistance rates were higher in animal isolates than human isolates. In animals, resistance of *Salmonella* from poultry sources was higher than cattle (Bjork et al., 2015). Antibiotic resistance patterns also show geographical variations. For example, ciprofloxacin resistance rates in broilers in the EU were 53%, whereas in the US nearly all *Salmonella* strains isolated from broilers were susceptible to ciprofloxacin. Furthermore, resistance rates fluctuated between the European

countries. For example, ciprofloxacin resistance rates in Denmark were zero, while in Hungary resistance rates reached 91% (McDermott et al., 2018).

Salmonella serotypes show geographical clustering. For example, while *S. Sofia* is a rare serotype in rest of the world, it is the most prevalent serotype in poultry products in Australia. In addition to regional differences, *Salmonella* serotypes show matrix based differences as well. For example, in Europe Typhimurium is the most prevalent serovar in pigs, whereas Enteritidis is the most prevalent in poultry. In general, Typhimurium and Enteritidis are the two serotypes that show global presence, despite the regional differences are observed for the rest of the serovars (Ferrari et al., 2019). In fact, spread of Enteritidis is considered as an ongoing pandemic which was emerged in 80s. It was believed that dispersal of this serotype was associated to globalization of poultry supply chain. In addition, feed contamination was another likely source for the spread of Enteritidis (Li et al., 2021). Similarly, spread of multidrug resistant strain Typhimurium (DT4) was considered as global epidemic during the 90s. main driver of dissemination of that strain was thought be animals and foods (Mather et al., 2013a). Infantis, Kentucky, Derby, and Agona serovars also distributed globally. (Singer et al., 2009) showed that some serotypes show more competitiveness than others, and cultivation media and method also affects the bias.

One of the main sources of *Salmonella* is poultry and poultry products (Rajan et al., 2017). *Salmonella* contamination may occur in all steps of poultry production, from farm to process, storage, and distribution, and preparation (Abhisingha et al., 2020). One of the main contamination routes of *Salmonella* is through contaminated feed (Nair & Kollanoor Johny, 2019). Contamination might occur through a number of ways, and *Salmonella* might survive in dry feed for months (Jones, 2011). Although contamination route is complicated and hard to associate with, contamination in feed may introduce *Salmonella* into supply chain (Harrison et al., 2022). Several feed additives have been proposed to tackle *Salmonella* in feed, including prebiotics and probiotics (Maciorowski et al., 2006). Before their ban due to resistance concerns, antibiotics had been used for over 50 years as feed additive (Dibner & Richards,

2005). Bacteriophages have also been emerged as a viable feed additive (Nair & Kollanoor Johny, 2019).

In a comprehensive study in Turkey, 35.9% of the 417 broiler was found to be contaminated with *Salmonella*. In addition, *Salmonella* isolation rate was 24.5% and 12.5% for the mats and feed, respectively. *Salmonella* isolates were grouped under 22 serotypes. Infantis was the most prevalent serotype, 76.5% of the isolates were Infantis. Kentucky, Enteritidis, Senftenberg, Mbandaka, Hadar, and Typhimurium serotypes were also found. Almost all of isolates were found resistant against at least one antibiotic. Furthermore, 460 of 652 Infantis isolates, and 104 of 121 Kentucky strains were multidrug resistant (Gıda ve Kontrol Genel Müdürlüğü, 2018). In another study antimicrobial resistance of 99 *Salmonella* that were isolated from chicken carcasses was investigated. More than half of the isolates were found to be resistant two or more antibiotics (Zafer et al., 2015).

Salmonella contamination in poultry products in Turkey was reported to be high (Acar et al., 2017; Gıda ve Kontrol Genel Müdürlüğü, 2018). Studies also showed that isolated *Salmonella* serovars showed multi drug resistance. In our previous studies, prevalent serovars in Turkey were Infantis, Typhimurium, Montevideo, Kentucky, Enteritidis, and Telaviv (Acar et al., 2017). In another study, Infantis, Kentucky, Enteritidis, Senftenberg, Mbandaka, Hadar, and Typhimurium were reported as the most prevalent serotypes (Gıda ve Kontrol Genel Müdürlüğü, 2018). In our latest study, we found that Liverpool was a prevalent serovar in food and environmental samples in Ankara region (Tok et al., 2022). In that study, 66% of the *Salmonella* isolates showed multidrug resistance. Successful previous examples of Denmark and the Netherlands showed that fighting with foodborne diseases should be localized. A national burden of foodborne disease estimate should be conducted by authorities based on the scientific data (Pires et al., 2021). For *Salmonella*, all of these studies showed that serotype distribution of *Salmonella* was dynamic and needs to be monitored regularly. Furthermore, antibiotic resistance of *Salmonella* strains isolated from poultry in Turkey was high and needs to be reduced.

2.2 Bacteriophages

Bacteriophages were discovered by Felix d'Herelle in 1917 (Summers, 2016). Phages are the most abundant and diverse organisms on earth (Dion et al., 2020). It is estimated that total phage number is nearly 10 times more than bacteria (Żbikowska et al., 2020). They have major roles in every environment, from biochemical cycling in oceans, to modulating human metabolism through lysogeny in human gut microbiota (Kim & Bae, 2018). *Salmonella* and *E. coli* phages have recovered from human stool (Fortier & Sekulovic, 2013; McGrath & Sinderen, 2007).

Phages are the main driver of evolution of pathogenic bacteria (Fortier & Sekulovic, 2013). Lysogenic phages provide many benefits to its host; such as toxin production in *Corynebacterium diptheriae*, *Clostridium botulinum*, *Vibrio cholera*, and *E. coli* O157:H7 (Brüssow et al., 2004), sporulation in *Clostridium* (Postollec et al., 2012) and *Bacillus cereus* (Boudreaux & Srinivasan, 1981), virulence in *Salmonella enterica*, *Staphylococcus aureus*, and *Streptococcus pyogenes* (Aziz et al., 2005; Cooke et al., 2007). In addition to these well-known examples, prophages are also involved in biofilm formation, viral resistance, and antibiotic resistance of host (Fortier & Sekulovic, 2013; Wang et al., 2010).

Phages had been used as an antimicrobial agent until the discovery of antibiotics. Recently, phages have started gaining popularity due to high prevalence of antimicrobial resistance. One of the most important features of phages is the limited host range. It was shown in different applications that phages do not harm natural microflora, animal or human cells. Moreover, Food and Drug Administration (FDA) declared the status of several commercial phage cocktails GRAS (Hagens & Loessner, 2010). In addition, a number of phage products were Halal and Kosher certified (Moye et al., 2018).

2.2.1 Bacteriophage classification

Classification of phages, or viruses in general, has always been complicated. Initially, tailed phages (*Caudovirales*) were grouped under 3 morphologies; contractile tail, long non contractile tail, and short non contractile tail (Turner et al., 2021). Later, the main three family of tailed phages were named as *Myoviridae*, *Siphoviridae*, and *Podoviridae*. Classification of phages took a big leap with the introduction of electron microscopy (Ackermann, 2011). This allowed the morphology based classification. In 1970s, David Baltimore introduced another classification method based on genome type and relation to mRNA synthesis. According to that scheme, phages were classified under seven groups; double stranded (ds)DNA, single stranded (ss)DNA, double stranded (ds)RNA, single stranded (ss)RNA, positive sense RNA, negative sense RNA, and reverse transcribing DNA. This system is very useful as it still is used today, but it is missing evolutionary relationship of viruses (ICTV, 2020).

With the rapid emergence of genomics, phage sequences provided magnitudes of more resolution compared to previous techniques. Therefore, instead of host range or physical features based classification, a genome based taxonomy was proposed (Rohwer & Edwards, 2002). More than 96% of known phages are tailed ds DNA phages (Żbikowska et al., 2020). Bacterial and Archaeal Viruses Subcommittee of ICTV adopted a new genome based taxonomy approach. In the 1999 ICTV reported consisted of three families and 30 species. On the other hand, 2018 report had 5 families and 1320 species (Dion et al., 2020). Very recently, new families have been derived from *Myoviridae*, *Siphoviridae*, and *Podoviridae* (Turner et al., 2021). ICTV accepts proposals, and with the rapid increase in the number of phage genomes on databases, new families and subfamilies are expected in near future (Aiewsakun & Simmonds, 2018).

2.2.2 Bacteriophage structure

Based on their morphology phages are investigated under 3 families; *Myoviridae*, *Siphoviridae*, and *Podoviridae*. Although their enormous diversity, phages have a basic structure design; a head, consisting of a capsid, a protective protein coat, which is containing genetic material, and a tail which is essential for infection (Figure 2.1). Bacteriophage structure has been studied for decades with different visualization techniques from X-ray crystallography to nuclear magnetic resonance, and most importantly, electron microscopy (White & Orlova, 2019). The resolution has been vastly increased, and protein structures of capsids of well-known phages like T4 (Chen et al., 2017), T5 (Vernhes et al., 2017), and P22 (Parent et al., 2010) has been explained in detail. Vast majority of phage heads have an icosahedral shape. Ackerman recorded the diameter of the head of more than 100 *Salmonella* phages in electron microscope, and measurements were in range between 44 to 104 nm (Ackermann, 2007).

Figure 2.1 Morphology and structure of phages. Image was taken from Nobrega et al. (2018) with permission.

Phage tail structure differ between the families. *Myoviridae* has a contractile tail, *Siphoviridae* have long, elastic, and non-contractile tail, and *Podoviridae* have short

non contractile tail (Turner et al., 2021). At the distal end of the tail, there are tail fibers and tail spikes. These tail fibers and spikes are attached to a base plate in *Myoviridae* and *Siphoviridae*. However, since tail is short in *Podoviridae*, tail fibers and spike is directly attached to tail (Nobrega et al., 2018). The tail of *Salmonella* phages belong to *Podoviridae* were less than 20 nm, whereas *Siphoviridae* family might reach up to 280 nm length (Ackermann, 2007).

2.2.3 Bacteriophage infection mechanism

Phage infection always starts with physical interaction between phage and host. Initial contact occurs by diffusion or Brownian motion (Harada et al., 2018). The receptor binding proteins presented at the tail fibers of phages, recognize the receptors on the bacterial surface and two step binding is initiated. First stage is reversible binding, in which the adsorption is not complete and phage could desorb (Dowah & Clokie, 2018). The surface receptors on bacteria are including, glycoproteins, lipopolysaccharides, amino acids, teichoic acids, or flagella and pili (Harada et al., 2018). Since cell structures of Gram-positive and Gram-negative bacteria are different, phage binding receptors differ. For example, main binding receptor of Gram-negative bacteria is the lipopolysaccharide (LPS) layer. Tail fibers of phage recognize O-antigen on LPS, and hydrolyze it for the penetration of tail (Golomidova et al., 2016). On Gram-positive bacteria, phages mainly attach teichoic acid. However, Xia et al. (2011) showed that phages from different families prefer different binding sites. For example, *Siphoviridae* prefer substituent groups, while *Myoviridae* binds the backbone. Phages are also reported to bind flagella (Choi et al., 2013), pili (Chibeu et al., 2009), and capsule (Pickard et al., 2010). In addition to infection, host range of phage is determined by the attachment of receptor binding proteins on tail fibers (Abdelsattar et al., 2021). In general, phages are monovalent, they can infect only a narrow strain range. Polyvalent phages that can infect multiple strains are rare in nature.

In the second stage, irreversible binding occurs as a result of adsorption of the receptor. Multiple tail fibers bind to receptors, and baseplate conformation of phage changes. Then, tail spike binds the host receptor irreversibly. In case of *Myoviridae*, binding and baseplate configuration change occur, tail contracts for the ejection of genetic material. (Nobrega et al., 2018). After irreversible binding, phage inject its DNA into the host cell by cleaving host membrane with its enzymes (Bertozzi Silva et al., 2016). A number of proteins have a role in DNA injection into host cell. These proteins are called membrane penetrating proteins, and structurally different than tail fiber. Although main function of membrane penetrating proteins, they might be associated with host range (Nobrega et al., 2018). In addition to membrane penetration proteins, phages also consist of lytic enzymes for local degradation of bacterial membrane. These enzymes are grouped under 5 classes based on their specificity; lytic transglycosylases, endopeptidases, N-acetyl-muramoylamidases, lysozymes, and N-acetyl- β - δ -muramidases.

After injection, phage genome must be protected from bacterial exonuclease degradation. For that, phage has a small specific site named *cos* region. This region helps DNA circularization. Host enzyme, DNA ligase seals the *cos* site at the either hand to produce circular DNA. Another host enzyme, DNA gyrase supercoils the phage DNA (Trun & Trempy, 2009).

2.2.4 Bacteriophage lifecycle

Bacteriophages are called lytic or temperate (lysogenic) based on the path they followed after infection. Lytic phages lyse the host after an infection cycle, while temperate phages integrate their genetic material into the host DNA. Temperate phages can initiate lytic cycle based on some environmental responses. However, due to the unpredictable nature temperate phages are not preferred in phage applications (Chan et al., 2013). Lytic phages lyse the bacteria with a mechanism called as “lytic cycle”. Lytic cycle is consisted of mainly 4 stages. Attachment of the phage is the first stage of infection in which phages recognize specific binding sites (e.g. outer membrane

proteins, teichoic acid) on the host membrane with the specialized proteins in tail fibers. In the second stage of infection, penetration, phage inject its genetic material into the cell by either mechanical force or with lysozyme activity. Third stage is called as biosynthesis or redirection. At this stage, phage viral components are produced by hosts synthesis mechanisms. In the next stage, maturation, newly formed viral components are assembled to form virions. At the final stage, release, host cell is lysed by lytic enzymes such as lysin, holin and murein, and virions are released into environment (Drulis-Kawa et al., 2012).

Lysogenic relationship between phage and host is very complex, and may result in different outcomes. Lysogenic pathway of phage λ is used as model. According to Brady et al. (2021), phage decides lytic or lysogenic pathway based on the environmental responses. There are two main regulators that control lytic lysogenic switch; Cro and CI. Lysogenic pathway is regulated by CI, which repress lytic operators, while Cro controls lytic pathway (Brady et al., 2021). For instance, phages might enter pseudolysogenic life cycle. In this state, phage genome stays unintegrated to host, and transferred to only one daughter cell. This lifecycle often associated with stress conditions like, starvation. Phage might turn lytic or lysogenic when the stress conditions disappear (Monteiro et al., 2019). Lysogenic phages might turn in cryptic prophage due to gradual decay or genome rearrangements during the evolution. The cryptic prophages are unable to initiate lysis contrary to active prophages, and became a permanent part of host genome (Wang et al., 2010). For example, one of the most studied bacteria, *E. coli* K-12, has 9 cryptic phages which constitutes 3.6% of the total genome (Canchaya et al., 2003).

Phenotypically, one-step growth is a convenient and descriptive characteristic to describe the virus lytic life cycle. A cycle starts when the virus bind and penetrate the cell. This initial phase is called as latent period, and no viral particles are found in media at this stage. After the latent period, the burst occurs and newly formed virions are bursted out of cell. In this period, the number of viruses in the media is increased sharply, and is called as the one-step growth (Kropinski, 2018).

2.2.5 Bacteriophage application

An important feature of phages is the ability to be used in very diverse applications. There are a wide variety of reports of phage applications in medicine in the literature (Pirnay et al., 2019), environment (Ye et al., 2019), veterinary (Atterbury et al., 2007). In the recent years, pre-clinical and clinical studies involving phage or phage combinations have been widely popular due to potential of phages. For example, Altamirano et al. (2022) combined a phage and an antibiotic for treatment of *Acinetobacter baumannii* in vivo. Although *A. baumannii* was resistance to given antibiotic, bacteria become susceptible again. In foods, phages can be used as antimicrobial agents. In addition, phage enzymes, endolysins can also be utilized as agents (Lee et al., 2022). Phage applications can be evaluated in 4 main groups; therapy, sanitation, control and prevention. Sanitation is the application of phages on food contact surfaces. Phage applications in pre-harvest or pre-slaughter is called as therapy, in process named as control, and after process (e.g.) storage is called as prevention (Greer, 2005).

Phages can be used as biocontrol agents in farm animals for therapeutic purposes. In a study, phages were applied to poultry orally as a feed additive, and 1.3 log reduction in *Salmonella* population was observed (Sklar & Joerger, 2001). In a similar study, phages reduced *Salmonella* population by 3.5 log in broiler, when applied orally as an additive (Fiorentin et al., 2005). Borie et al. (2008) reported that *Salmonella* colonization in digestive track was completely prevented with phage application. Landers et al. (2014) showed that phages could be used as growth promoter in farm animals as an alternative to antibiotics.

Phages can also be used in processing stage for biocontrol of foodborne pathogens. Bacteriophage addition to milk during cheese production prevented *Salmonella* growth for 89 days (Modi et al., 2001). Abdelsattar, Safwat, et al. (2021) used a monophage to reduce *Salmonella* Enteritidis contamination in milk. After 3-hour incubation at 37 °C, phage reduced *Salmonella* population by 10³.

Bacteriophages are also viable sanitation agents, as they are reported effective against biofilms in various foodborne pathogens including *Salmonella* (Islam et al., 2019), *E. coli* (Lee & Park, 2015), and *Vibrio* (Sasikala & Srinivasan, 2016). In another study, a phage cocktail containing 6 phages was applied to reduce *Salmonella* population on glass and steel surfaces. Phage cocktail reduced the *Salmonella* population by 2-4 logs on surfaces (Woolston et al., 2013). In the same study, researchers used *S. Paratyphi B* as the target on surface. Phage cocktail was ineffective against *Paratyphi B* in initial experiments. However, when two of the phages were replaced with *Paratyphi* targeting phages, phage cocktail significantly reduced the *Paratyphi B* on the surfaces. Authors stated that the results showed the flexibility of phage application (Woolston et al., 2013).

There are a number of FDA approved phage based biocontrol agent that targets *Salmonella*, including but not limited to SalmoFresh™ by Intralytix (US), PhageGuard-S by PhageGuard (Netherlands), Armament by Omnilytics (US), and Biotector by Cheiljedang (South Korea). These products are sprayable to food and food contact surfaces. These products are included in the USDA Food Safety and Inspection Service (FSIS) list for safe products for chicken and meat process. Moreover, some of those products (e.g. SalmoFresh) has halal certification. However, due to the nature of phages, these products were prepared for specific serotypes, and may not affect others. For example, SalmoFresh targeted Typhimurium, Enteritidis, Heidelberg, Newport, Hadar, Kentucky, Thompson, Georgia, Agona, Grampian, Senftenberg, Alachua, Infantis, Reading, and Schwarzengrund. On the other hand, Biotector targets poultry pathogens, Gallinarum and Pullorum. Host ranges of commercial phages indicates the need of more local targeted phage products. For instance, in our previous studies we discovered Telaviv and Liverpool were two emerging serotypes in Turkey. As a result, current commercial products may not be effective in Turkey. For a successful phage product, first most prevalent and most infectious serotypes in that region must be determined, and a target based product must be developed. A similar observation was made by Moreno Switt et al. (2013). Host range of 108 phages isolated from 10 different farms

were investigated. While 51% of phages showed narrow host range, remaining phages infected a broad range of hosts. In the same study, it was determined that there is a correlation between the isolated phage and their hosts. For instance, if the dominant serotype was Enteritidis in a farm, isolated phages from that farm was generally effective against Enteritidis (Moreno Switt et al., 2013).

Timing, delivery method, and titer are the key factors in phage application (Atterbury et al., 2007). Phages are generally applied in solution in food and farm applications (Han et al., 2022). Phages might be developed in powdered or tablet form. Vandenhuevel et al. (2013) dried phages in a spray dryer with lactose, dextrose, and trehalose. In that study, phage titer was significantly dropped when dried with lactose and dextrose. However, trehalose addition was found successful in phage drying. Even with the successful drying application with trehalose, phages powder had to be kept under a certain temperature and relative humidity (Landers et al., 2014). Lyophilization is another drying application that shows promising results. Merabishvili et al. (2013) lyophilized phages with sucrose and trehalose addition, successfully stored for more than 2 years with a stable titer. Chan et al. (2013) described several aspects for a successful phage therapy experiment; First of all, phage must be strictly lytic. Secondly, phage must successfully lyse the representative strains of host. Moreover, models should represent the real life scenarios. Authors stated that purification through filtration would be sufficient for in vitro models (Chan et al., 2013). Furthermore, rapid development in synthetic biology created a lot of promising therapy options. For example, Monteiro et al. (2019) reviewed the phage therapy methods involving temperate phages. Advances in bioengineering enabled the development of lytic phages from temperate phages.

2.2.6 Bacteriophage application on poultry production

Ability of phages to reduce *Salmonella* in all stages of poultry chain has been studied extensively. Atterbury et al. (2007) tested the ability 3 phages to reduce cecal colonization *Salmonella* in broiler. Phages were administered orally with an antacid

suspension. After 24 hours, when treated with their phages, *Salmonella* Enteritidis and *Salmonella* Typhimurium loads were reduced by 4.2 and 2.19 log CFU, respectively. However, Hadar phage was unable to reduce Hadar population. Authors explained the ineffectiveness of Hadar phage might be due to the phage resistance developed during the treatment (Atterbury et al., 2007). In a similar study, Bardina et al. (2012), tested a phage cocktail against *S. Typhimurium* in mouse and chicken models in vivo. In mouse models, authors reported 50% survival was achieved when cocktail was given with infection. In chicken models, significant reductions were obtained when phage cocktail applied pre-infection. In a comprehensive study, Clavijo et al. (2019) tested a commercial phage cocktail (SalmoFREE®) in two field trials with nearly 35000 broilers each. In each trials there were a control farm as well. Researchers added the phage cocktail and control suspension to drinking water of broilers for trial and control groups, respectively. After a production cycle (33 days) *Salmonella* prevalence in cloacal swabs was 0%, whereas *Salmonella* positive samples were observed in control farm. Researchers also reported that phage cocktail didn't affect broiler production parameters, or broiler behavior. The results showed that phages might be used against *Salmonella* in poultry production without affecting the production quality (Clavijo et al., 2019).

Phages also tested as a post slaughter control tool against *Salmonella*. Higgins et al. (2005) designed two experiments to test the efficacy of phages against *S. Enteritidis*. In the first experiment, authors treated carcass rinse waters with a single phage. Secondly, they artificially contaminate the carcass with *S. Enteritidis*, and sprayed the phage in different concentrations. Authors reported significant reductions in *S. Enteritidis* populations in all experiments (Higgins et al., 2005). Phage biocontrol of *Salmonella* on chicken carcasses was also studied by a different study design (Atterbury et al., 2020). Broiler chickens were infected with *S. Enteritidis* and *S. Typhimurium*. Animals were euthanized 7 days later, and 25 cm² area of skins were recovered. Respective phage suspensions were sprayed onto samples, and SM buffer were sprayed to control samples. After incubation period *Salmonella* colonies counted with most probable number (MPN) method. While Enteritidis phage

reduced Enteritidis counts by 1.38 log MPN, Typhimurium phage reduced Typhimurium population by 1.83 log. Both of the reductions were found significant compared to control (Atterbury et al., 2020).

Phages were found effective during the various processing steps of poultry. In a study, trimmed poultry were inoculated with *Salmonella* to a final concentration of 7 log CFU/g in ground product. A commercial phage suspension was added during the tumbling process at levels 10^8 plaque forming unit per mL (PFU/mL). After samples held at 4 °C for 6 hours, phage reduced *Salmonella* population by 1.1 and 0.9 log in chicken and turkey, respectively (Yeh et al., 2017). Sukumaran et al. (2015) evaluated the effectiveness of a commercial phage (SalmoFresh) when applied combined sequentially or combined with various antimicrobials in poultry cuts. The authors reported that combination phage and lauric arginate reduced *Salmonella* by 1.3 log. When the phage and peracetic acid was applied in sequence, the reduction reached 2.5 log (Sukumaran et al., 2015).

Phage application during storage at various temperatures was studied by different groups. Bao et al. (2015) tested phages against *Salmonella* on chicken breast at 4 °C and 25 °C. Phage suspension reduced *Salmonella* population significantly (1.65 log) after 5-hour storage at both temperatures. Authors reported that a bigger reduction in *Salmonella* numbers was observed at 4 °C (Bao et al., 2015). Contrarily, Duc et al. (2018) reported bigger reduction was observed in 25 °C. In that study, chicken pieces were artificially contaminated with *S. Enteritidis* and *S. Typhimurium*, and treated with a phage cocktail at 8 °C and 25 °C. 1.41 log and 1.86 log reduction was observed for Enteritidis and Typhimurium, respectively at 8 °C. However, reduction was 3.06 log and 2.21 log for Enteritidis and Typhimurium at 25 °C (Duc et al., 2018). Abhisingha et al. (2020) used a phage cocktail to reduce *Salmonella* Typhimurium on chicken. Artificially contaminated chicken meat was treated with phage cocktail, and stored at 4 °C and -20 °C for 24 hours. Significant reductions in *Salmonella* population were observed in both storage conditions. Combination of a commercial phage cocktail and packaging conditions on *Salmonella* during storage was studied. *S. Typhimurium*, Heidelberg, and Enteritidis were treated with phages

(10^9 PFU/mL), and stored up to 7 days in two different packaging conditions; aerobic and modified atmosphere (95 CO₂ and 5% O₂). Phages reduced the *Salmonella* counts significantly in both packaging. Highest reduction was observed when MAP and phage cocktail combined (Sukumaran et al., 2016).

CHAPTER 3

MATERIALS AND METHODS

3.1 Chemicals and materials

A list of chemicals, materials and the commercial manufacturers of those materials are presented in the Appendix J. All of the substances used in the study were analytical grade.

3.2 Sample collection

In the study, samples from farms in different cities were collected. Cities in the study were Adıyaman, Şanlıurfa, Ankara, Bolu, and Denizli. Cities were selected from different regions to provide phage and *Salmonella* diversity. Adıyaman and Şanlıurfa samples were kindly provided by Prof. Dr. Yasar Osman Tel. 100 g samples were collected in sterile cups with sterile spoons from each farm. From wastewater facility, 100 mL sample was collected in sterile 50 mL tubes. Samples were brought to lab as soon as possible without breaking the cold chain. Samples were taken in 11-month span to observe the effect of seasonal changes and shifts on *Salmonella* and bacteriophages.

A total of 57 sample was collected in 11 months (Table 3.1). 25 samples were collected from Adıyaman. 5 different farms were visited in 5 different months. Similarly, 5 farms in Şanlıurfa were visited in 4 different months. In Denizli, 3 different farms were visited in June, while 5 farms were visited in Bolu, in August. METU wastewater facility was visited in 4 different months in order to increase sample diversity.

Table 3.1 Sampling dates and locations

| Month | Sampling Sites | | |
|-----------|--------------------------|--------------------------|--------------------|
| February | Adiyaman (n=5) (2P, 3C) | Şanlıurfa (n=5) (2P, 3C) | |
| June | Adiyaman (n=5) (2P, 3C) | Şanlıurfa (n=5) (2P, 3C) | Denizli (n=3) (3P) |
| August | Adiyaman (n=5) (5P) | Bolu (n=5) (5P) | Wastewater (n=1) |
| September | Şanlıurfa (n=5) (2P, 3C) | | |
| October | Adiyaman (n=5) (2P, 3C) | | Wastewater (n=1) |
| November | Adiyaman (n=5) (2P, 3C) | Şanlıurfa (n=5) (2P, 3C) | Wastewater (n=1) |
| December | | | Wastewater (n=1) |

n: Total number of samples P: samples collected from poultry farms, C samples collected from cattle farms

3.3 *Salmonella* isolation

Samples collected for phage isolation, was also used for *Salmonella* isolation, synchronously. Isolation of *Salmonella* was carried out as described by ISO 6579:2002 protocol. Briefly, 25 g farm sample or 25 mL wastewater sample was added into 225 mL buffered peptone water (BPW) and homogenized for 1 minute. Samples were incubated 20±4 hours at 37 °C for pre enrichment. Then, 100 µL mixture was taken from stomacher bag, and added onto rappaport vassiliadis soy (RVS) broth. Broths were incubated for overnight, and 10 µL sample were plated onto xylose lysine desoxcholate (XLD) agar plates by spread plate. After another incubation for 24 hours at 37 °C, suspected colonies (black with transparent halo) from plates were transferred onto brain heart infusion (BHI) agar. For each sample 3 different colonies were picked and transferred separately. When too many colonies grew on plates, serial dilutions were prepared from RVS broth, and spread plate was performed for each dilution.

3.4 Molecular confirmation of *Salmonella* isolates

Salmonella confirmation was done via polymerase chain reaction (PCR) screening of *invA* gene (Rahn et al., 1992). Single colonies from suspected isolates were streaked onto BHI agar and incubated for 18 hours. After incubation, single colonies from BHI agar were taken with a sterile stick and transferred into a 0.2 mL PCR tube containing 95 μ L sterile distilled water. Cells were ruptured with microwave treatment for 30 seconds. 1 μ L of lysed cell solution were added to master mix tube. PCR master mix and *invA* primer sequences are given in Table 3.2.

Table 3.2 PCR Master Mix and *invA* primer sequence

| PCR Reaction Solution [Concentration] | Primer sequence 5' -3' | Volume (μ l) |
|---------------------------------------|--------------------------|-------------------|
| dH2O | - - - | 17.5 |
| 5X Go Taq Flexi buff | - - - | 5 |
| <i>invA</i> -F [12.5 μ M] | GAATCCTCAGATTTTCAACGTTTC | 0.5 |
| <i>invA</i> -R [12.5 μ M] | TAGCCGTAACAACCAATACAAATG | 0.5 |
| Taq DNA polymerase | - - - | 0.5 |
| TOTAL | | 24 |

For each isolate, 24 μ L master mix and 1 μ L lysed cell was added into PCR tubes. Then, *invA* gene region (678 base pairs) was amplified by T100™ Thermal Cycler (Bio-Rad) with the conditions given in Table 3.3.

Table 3.3 Amplification conditions of *invA* gene

| Temperature (°C) | Time | Cycles |
|------------------|--------|--------|
| 94 | 8 min | 1 |
| 94 | 30 sec | |
| 60 | 30 sec | 35 |
| 72 | 30 sec | |
| 72 | 5 min | 1 |
| 4 | ∞ | 1 |

5 µL PCR products was run at 110 V for 50 min in a 1.5% agarose gel in gel electrophoresis. A ladder with known molecular weight and a positive control (MET S1-001, *Salmonella* Enteritidis) was added. Bands were displayed after staining in ethidium bromide (Et-Br) solution for 5 minutes, following by a 30 minutes destaining in ddH₂O. Gels were visualized under UV light (Biorad-Gel Doc XR Documentation System, USA). Lanes with a band at 678 bp was confirmed as *Salmonella*. A single colony from confirmed isolates was put into 5 mL BHI broth, and was incubated for 16 hours. 850 µL of isolate was mixed with 150 µL glycerol solution, and frozen -80 °C for further experiments. All the isolates were labeled, and frozen in triplicate.

3.5 Genomic characterization of *Salmonella* isolates

Genomic relatedness of analysis was done by PFGE (Acar et al., 2017). For this experiments, isolates were streaked onto BHI agar and incubated for 20±4 hours at 37 °C. Colonies were collected with a sterile cotton swab and transferred cell suspension buffer (CSB). Concentrations were adjusted by spectrophotometer (OD₆₁₀:1.3-1.4). Adjusted suspensions were immediately taken on ice until the experiment. From each suspension 400 µL were transferred into 1.5 mL centrifuge tubes and incubated at 37 °C for 10 minutes. After incubation, 20 µL Proteinase K solution (20 mg/L) was added into each tube. Samples then mixed with 400 µL 1%

SKG agarose with %1 SDS solution in plug molds. Mixture was held in room temperature for 15 minutes to solidify. For each sample, 5 mL cell lysis buffer (CLB) and 25 μ L Proteinase K solution (20 mg/L) were put into 50 mL falcon tubes. Solidified plugs were transferred into labeled falcon tubes, and tubes were incubated for 2 hours at 54 °C in shaking incubator (170 rpm). After incubation, plaques were washed with sterile ddH₂O two times and tris-EDTA (TE) buffer four times. TE and ddH₂O was held in water bath (55 °C) prior to washing. In each washing step, a filter was attached to tubes, then all liquid content was discarded, and replaced with ddH₂O and TE according to washing step. After fresh ddH₂O or buffer addition, tubes were incubated in a shaking incubator at 55 °C. After washing, plaques stored in TE solution at 4 °C. Next day, plaques were cut in 2mm sizes and placed in the agarose gel.

Plaques of samples and reference strain were cut in 2 mm size, and placed into 1.5 mL centrifuge tubes. 200 μ L H buffer (175 μ L ddH₂O; 20 μ L H buffer; 5 μ L Xba1) was added, and the tubes were incubated for 10 minutes at 37 °C. After 10 minutes, H buffer was replaced with XbaI solution (175 μ L ddH₂O; 20 μ L H buffer; 5 μ L Xba1) and incubated for 4 hours at 37 °C. 2.2 L running buffer (0.5% TBE) was loaded into PFGE tank and, the system was started in order to cool the buffer to 15 °C. After the incubation, plaques were loaded into 1.5% SKG agarose gel. Wells on the gel was sealed with sealing agarose. Before the run, approximately, 1.5 mL thiourea solution was added to running buffer. The gel run in DNA-Chef DR III Biorad electrophoresis system with the conditions in Table 3.5. After running for 19 hours, the gel stained in Et-Br solution for 45 minutes, and destained in ddH₂O for 30 minutes. The gels than visualized under UV light in Biorad-Gel Doc XR Documentation System. The gel pictures were loaded into Bionumerics software (Applied Maths, Belgium) for clustering analysis. Dice coefficient was used similarity analysis, and clustering was performed by using unweighted pair group method by arithmetic mean (UPGMA).

3.6 Antibiotic resistance characterization of *Salmonella* isolates

Antimicrobial resistance of *Salmonella* isolates was characterized by using disc diffusion method suggested by European Union Committee on Antimicrobial Susceptibility Testing (EUCAST, 2015). 18 different antibiotics from different classes were screened (Table 3.4). Briefly, *Salmonella* isolates were inoculated into MHB and incubated for 20±2 hours at 37 °C. After incubation, concentration of isolates was adjusted with a densitometer (Biosan Den 1B) to 0.5 McFarland which is equal to 1×10^8 by using 0.9% NaCl solution. After that, bacteria were taken with cotton swab from NaCl solution and carefully streaked onto MHA plates. Antibiotic disks (Oxoid) were placed onto plates with the help of an antibiotic disk dispenser.

Plates were incubated for 18 hours at 37 °C, and zone diameters were recorded for each antibiotic. Data was processed in Excel, and a heatmap was created based on susceptibility data.

Table 3.4 Antibiotic agents, disk contents and diameter zones used in phenotypic characterization (EUCAST, 2015).

| Antimicrobial agent | Disc Content (μg) | Diameter zone (mm) | |
|-------------------------------|-----------------------------------|--------------------|-----|
| | | S \geq | R < |
| Amikacin | 30 | 18 | 18 |
| Gentamicin | 10 | 17 | 17 |
| Kanamycin | 30 | 18 | 13 |
| Streptomycin | 10 | 15 | 11 |
| Ampicillin | 10 | 14 | 14 |
| Ceftiofur | 30 | 21 | 17 |
| Cefoxitin | 30 | 19 | 19 |
| Ceftriaxone | 30 | 25 | 22 |
| Cephalothin | 30 | 18 | 14 |
| Amoxicillin-clavulanic acid | 20/10 | 19 | 19 |
| Ertapenem | 10 | 25 | 25 |
| Imipenem | 10 | 22 | 22 |
| Chloramphenicol | 30 | 18 | 12 |

| Pefloxacin | 5 | 24 | 24 |
| Tetracycline | 30 | 15 | 11 |
| Trimethoprim-sulfamethoxazole | 1.25/23.75 | 16 | 10 |
| Sulfisoxazole | 300 | 12 | 12 |

3.7 Bacteriophage isolation

Phage isolation was carried out as soon as the samples were transferred to lab. Isolation was carried out according to Moreno Switt et al. (2013) and Bonilla et al. (2016), with small modifications that were explained below for wastewater and farm samples.

3.7.1 Bacterial strains

Since phages are obligatory parasites and requires a host to replicate, various *Salmonella* strains were used in phage isolation. For phage isolation, 8 different isolates representing most prevalent *Salmonella* serotypes were selected from our culture collection (Table 3.5). The serovars were selected according to (I) their prevalence in human, animal, and food samples in Turkey and the EU (WHO, 2021), (ii) their relation to previous foodborne outbreaks (iii) their prevalence in poultry (Gıda ve Kontrol Genel Müdürlüğü, 2018; EFSA, 2021). All strains were isolated from food sources previously and were kept at -80 °C. Two days before the experiment isolates were revived by streaking onto BHI agar. Isolates were incubated at 37 °C for overnight. Next day, a single colony from BHI agar was taken with a sterile loop and transferred into 10 mL Luria Bertani (LB) broth (Madrid, Spain). Isolates were incubated in LB broth at 37 °C for 18-20 hours, before used as host organism in isolation.

Table 3.5 *Salmonella* isolates that are used as target strains in phage isolation

| METUID | Genus | Species | Serotype | Resistance | | Date | City |
|------------|-------------------|-----------------|-------------|------------------|-------------------|------------|-----------|
| | | | | Profile | Source | | |
| MET S1-001 | <i>Salmonella</i> | <i>enterica</i> | Enteritidis | Susceptible | Chicken meat | 11/9/2005 | Ankara |
| MET S1-002 | <i>Salmonella</i> | <i>enterica</i> | Typhimurium | CipAzm | Chicken meat | 11/11/2005 | Ankara |
| MET S1-006 | <i>Salmonella</i> | <i>enterica</i> | Infantis | KKfSxtSfN Cip | Chicken meat | 11/7/2005 | Ankara |
| MET S1-015 | <i>Salmonella</i> | <i>enterica</i> | Montevideo | KSTSfN | Ground meat | 12/14/2005 | Ankara |

| MET S1-007 | <i>Salmonella</i> | <i>enterica</i> | Kentucky | Susceptible | Chicken meat | 10/10/2005 | Ankara |
| MET S1-248 | <i>Salmonella</i> | <i>enterica</i> | Anatum | Susceptible | Sheep ground meat | 7/18/2012 | Şanlıurfa |
| MET S1-163 | <i>Salmonella</i> | <i>enterica</i> | Hadar | KfAmpN | Cheese | 12/24/2012 | Şanlıurfa |

3.7.2 Phage isolation from manure samples

For farm samples, 10 g sample was weighted with sterile spoon and cup, and was transferred into a filtered stomacher bag. Sample was diluted with salt magnesium (SM) buffer (5.8 g NaCl, 2.0 g MgSO₄·7H₂O, 50 mL 1 M Tris-HCl pH 7.4, in 1 liter dH₂O). by 1:10 in stomacher bags for 2 minutes, and the put into shaker for two hours in room temperature. Then, samples were taken centrifuge tubes, and centrifuged for 10 minutes 9000 × g. After centrifugation, supernatant was taken, and the pellet was discarded. Samples were filtrated through 0.45 and 0.22 µm cellulose acetate filters, respectively. In farm samples, MET S1-001, MET S1-002 and MET S1-006 were used as host organisms (Table 3.5). For pre-enrichment, 5 mL filtrate and 100 µL of each target host strain (*S. Enteritidis*, *S. Typhimurium*, and

S. Infantis) were added to 5 mL 2 X tryptic soy broth (TSB), and were incubated in a shaking incubator at 37 °C overnight. Next day, samples were centrifuged for 10 minutes at 9000 × g and filtered through 0.22 µm filter to get rid of host bacteria and other contamination. Resulting solution was presumed as phage solution. The solution was labeled accordingly, and kept at 4 °C.

3.7.3 Phage isolation from wastewater samples

Wastewater samples were centrifuged directly without dilution at 9000 x g for 10 minutes. Supernatant was filtered through 0.22 µm cellulose acetate filter. For the pre-enrichment step, wastewater filtrates were separated into 3 aliquots with 5 mL each. Each aliquot was mixed with 5 mL 2 × TSB. All hosts are used in wastewater samples. For pre-enrichment, hosts were divided into 3 different groups according to their genetic relatedness and added to phage-TSB mixture, 100 µL each (Table 3.6).

Table 3.6 Host cocktails for pre-enrichment for phage isolation for wastewater

| Groups | Serotype |
|--------|-----------------|
| 1 | 100 µL- S1-001 |
| | 100 µL - S1-002 |
| 2 | 100 µL - S1-006 |
| | 100 µL - S1-007 |
| | 100 µL - S1-015 |
| 3 | 100 µL - S1-063 |
| | 100 µL - S1-163 |
| | 100 µL-S1-248 |

Pre-enrichment mixtures were incubated at 37 °C overnight. Next day, mixtures were centrifuged for 10 minutes 9000 × g, and filtrated through 0.22 µm cellulose acetate filter. Like in farm samples, resulting 3 solutions were labeled accordingly and were kept at 4 °C.

3.7.4 Double plaque assay

For both farm and wastewater samples, existence of phages in phage solutions was tested by double plaque assay. For this, 100 µL phage solution from isolation steps and 100 µL host were added into 4 mL semi solid (0.6% agar) LB agar. After shaking gently, semi solid agar was poured onto solid LB agar on plate. Plates were incubated for 20 ± 4 hours at 37 °C, and plaque formation was observed. Serial dilutions from phage solutions were prepared when the resulting petri contained too many phage plaques. For serial dilutions 900 µL 0.9% NaCl solutions were used. In that case, a double plaque assay by using NaCl solution instead of phage solution was also included as control. In this step, hosts were selected according to isolation type. For example, phage solutions from farm samples were tested against MET S1-001, MET S1-002, and MET S1-006 as these isolates were used as hosts. On the other hand, phage solutions from wastewater samples were tested against all hosts from Table 3.5.

3.8 Bacteriophage purification

Petri plates from double plaque assay were examined carefully to spot morphologically different phage plaque formations. Each morphologically different plaque was subjected to purification step. For purification, single and isolated plaques with different morphologies were selected and marked. After that, by using a pipet tip plaque was gently touched without disrupting the agar or rest of the plate. Pipet tip than dipped into 100 µL 0.9% NaCl solution to transfer plaques. A serial dilution was prepared with 900 µL 0.9% NaCl solutions up to 10⁻⁸ and double plaque

assay was conducted from 10^{-3} to 10^{-8} in order to obtain separated phage plaques in petri plates. The purification step was conducted at least 3 times or until a uniform plaque formation was observed. When the uniform plaque formation was reached, a single, well separated plaque was taken with a pipet tip into 100 μ L 0.9% NaCl solution, and double plaque assay was conducted directly from that solution in order to obtain fully lysed petri plate.

The series of dilutions were done up to 10^{-8} , in order to determine phage titer. Phage titer was calculated as follows;

Equation 3.1
$$\text{Phage Titer } \left(\frac{\text{PFU}}{\text{mL}} \right) = \frac{\text{Number of plaques}}{d * V}$$

Where d is dilution, and V is the inoculation volume.

3.9 Bacteriophage storage

Bacteriophage storage was performed as suggested by Fortier & Moineau (2009). Petri plate from the last step of purification was examined after overnight incubation. If fully lysed profile was observed, 10 mL SM Buffer poured onto the plate. Petri plate with SM buffer was incubated at room temperature for 30 minutes, and gently shaken in every 3-5 minutes. After incubation, SM buffer was transferred into a centrifuge tube, and centrifuged at $9000 \times g$ for 10 minutes. Supernatant was collected with a sterile syringe and filtered through 0.22 μ m filter. Titters of phages were determined before storage. To determine the titters, series of dilutions were done up to 10^{-11} , and double plaque assay was conducted from 10^{-6} and below dilutions. After overnight incubation, phage titer was calculated as formulated in Equation 3.1.

If the phage titer was above 10^8 PFU/mL, portions were prepared from purified phage lysate for different storage conditions (Figure 3.1). From the filtrate, 1 mL was transferred into 1.5 mL Eppendorf tubes. These lysates are labeled as working

solution, and stored at 4 °C. Another 1 mL was transferred into Eppendorf tubes and these tubes were stored at -20 °C. From the remaining lysate, 850 µL was mixed with 150 µL glycerol in the cyrotubes and stored at -80 °C. All the portions were prepared in triplicates. In one of the triplicates, chloroform solution was added 1:100 ratios (10 µL for 1 mL tubes) to prevent contamination.

Figure 3.1 Storage scheme of phages

All the stocks were labeled; a unique ID code was assigned (METU ID), and a database, which contains all relevant information regarding the phages was created.

3.10 Bacteriophage lysis profiles on different hosts

Lysis profiles of all phages were tested on various *Salmonella* isolates in order to determine the host range. Hosts were chosen from our culture collection based on these selection criteria; (i) Serotype is listed by EFSA as the most common disease

causing serotypes, (ii) Serotype is commonly isolated in studies conducted in Turkey, (iii) Serotype caused an outbreak in the last 10 years. Based on these criteria 36 isolates representing 19 different serotypes were selected as hosts (Table 3.7). For eligible serotypes, isolates from different sources, and isolates with different PFGE types were chosen. For example, 5 different Enteritidis isolates were tested as hosts. 2 of those were clinical, 2 were food, and the other was environmental isolate. 2 clinical isolates and 2 food isolates had different PFGE types.

Table 3.7 Information of *Salmonella* isolates used in host range determination

| METUID | Serotype | Antibiotic Resistance | Isolate Source | PFGE Type |

Host range of phages was determined as described by Moreno Switt et al. (2013) and Fong et al. (2017). Briefly, 100 μ L host were put into molten (50 °C) semi solid (0.6% agar) LB agar. Agar mixed gently and poured onto solid LB plate slowly. After soft LB agar was solidified (15 to 30 min), petri plates were divided 8 parts, and labeled with the ID codes of phages. In each part 5 μ L of corresponding phage was spotted. Plates were left in room temperature to let the droplet dry for 30 min,

then incubated overnight at 37 °C. The next day, formations were observed and spots were graded based on the scale below:

(+) complete clearing

(T+) clearing throughout but with faintly hazy background

(T) substantial turbidities throughout the cleared zone

(P) a few individual plaques

(-) no clearing

Results were recoded as an Excel table right after the analysis. To identify phages with similar lysis profiles, a cluster analysis performed. For this, Ward's method of binary distance for hierarchical clustering was deployed in R software (RStudio version 2022.02); (R Development Core Team, Vienna, Austria [<http://www.R-project.org>]).

3.11 One-step growth curves, latent periods and burst sizes

One step growth curves were determined as described by (Clokic et al., 2018). From the Table 3.9, representative phages were selected for Enteritidis and Typhimurium (MET P1-001), Kentucky (MET P1-137), Infantis (MET P1-091 and MET P1-179). In addition, MET P1-088 and MET P1-197 were also selected as representatives for Hadar and Anatum, respectively. Host bacteria was cultured into LB broth a day before the analysis. Also, 8 hours prior to analysis host cultured into another LB broth to obtain a mid-exponential log culture. Phage titer in this study was adjusted to 1×10^6 a day before the analysis. Before the analysis, concentration of mid-exponential log culture was adjusted to 10^8 by spectrometer ($OD_{600} = 0.1$) by using 0.9% NaCl solution. From that culture, 9.9 mL was transferred into a flask (Adsorption flask), and incubated for 5 min at 37 °C. 100 μ L of 10^6 phage solution was added into the Adsorption flask, and the flask was swirled gently and incubated

for another 5 minutes. From the adsorption flask, 1 mL of the mixture was transferred into a test tube containing 100 μ L chloroform. Tube was vortexed and put into an ice bath. Another 1 mL mixture was transferred into 9 mL pre-warmed LB broth (Flask B). After a mixing, 1 mL content from Flask B was transferred to 9 mL pre-warmed LB broth (Flask C). Then, in every 6 minute for 90 minutes, 100 μ L content from each of the flasks were plated with the overnight host culture using double plaque assay. At the end of the 90 minutes, 100 μ L control sample was used inoculated from the test tube with chloroform. After overnight incubation plaques were counted, and data was plotted in SigmaPlot 14 software. By analyzing the plot, latent period and burst size were also characterized (Figure 3.2). Latent period was determined from plot as the intersect between the initial count and the slope (end of Average 1 in Figure 3.2). Burst size were determined as average of final count (Average 2) divided by average of the initial count (Average 1).

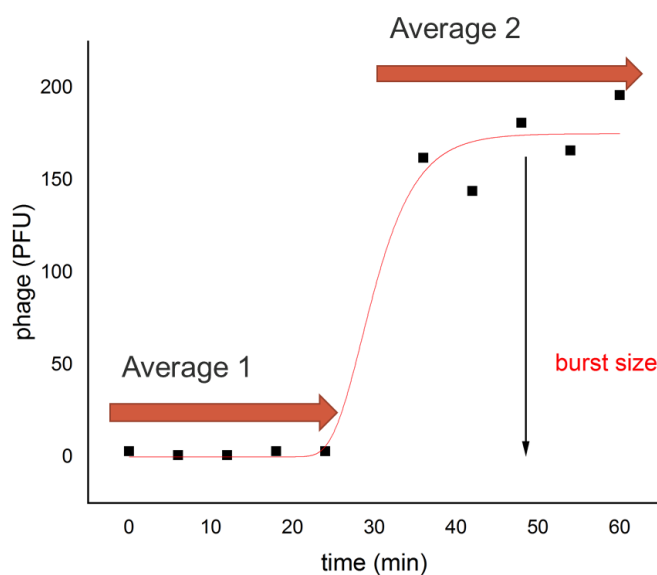

Figure 3.2 One-step growth curve, latent period estimation, and burst size determination

3.12 Adsorption rates

Attachment rate of bacteriophage to target cells were determined as described by Kropinski (2009). Similar to one step growth analysis, representative phages were selected for Enteritidis and Typhimurium (MET P1-001), Kentucky (MET P1-137), Infantis (MET P1-091 and MET P1-179). In addition, MET P1-088 and MET P1-197 were also selected as representatives for Hadar and Anatum, respectively. Host bacteria was cultured into LB broth a day before the analysis. Also, 8 hours prior to analysis host cultured into another LB broth to obtain a mid-exponential log culture. Phage titer in this study was adjusted to 1×10^5 a day before the analysis. Before the analysis, concentration of mid-exponential log culture was adjusted to 1×10^8 by spectrometer ($OD_{600} = 0.1$) by using 0.9% NaCl solution. 12 eppendorf tubes containing 950 μ L sterile LB broth was prepared, and labeled as A1-A10 and C1-C2. The tubes were ordered numerically, and chilled prior to experiment. 9 mL host culture with adjusted concentration was transferred into a sterile flask, and labeled as flask A. 9 mL sterile LB broth was transferred into sterile flask, and labeled as flask C for control. Both flasks were incubated at 37 °C for 5 minutes for temperature equilibrium, and after that 1 mL 1×10^5 phage suspension was added to flask A and flask C, and the timer was started. For 10 minutes, 50 μ L aliquot was transferred into eppendorf tubes starting with A1. Each eppendorf tube was vortexed and put back on ice. Similarly, after 10 minutes, 2 50 μ L aliquots were transferred into the tubes C1 and C2, vortexed, and put on the ice. After that 100 μ L from each tube was mixed with 100 μ L host in 4 mL soft LB agar poured onto LB agar. Plates were incubated for 24 hours at 37 °C, and plaques were counted. Plate counts were processed in Excel and a plaque vs time graph was drawn. Adsorption rate constant k was then calculated according to the equation;

Equation 3.2
$$k = \frac{2.3}{Bt} \log \frac{P_0}{P}$$

Where k is the adsorption rate constant, in mL/min; B is the concentration of bacterial cells; t is the time interval in which the titer falls from P_0 (original) to P (final).

3.13 Genome size estimation

Genome size of bacteriophages were determined by Pulsed Field Gel Electrophoresis (PFGE) as described by Lingohr et al. (2009) and Acar et al. (2017). *Salmonella* Braenderup (MET S1-713) was used as reference. Fresh high titer phages ($>1 \times 10^8$ PFU/mL) were prepared for the analysis. To remove any bacterial contamination, phage lysates were centrifuged at $6250 \times g$ for 15 minutes and filtered through 0.22 μm filter. 400 μL 1% Seakem Gold (SKG) Agarose were mixed with equal amount of phages filtrate, and mixture was loaded in to gel cast to create plaques. After the gel was solidified, plaques were put in to 50 mL tubes containing phage lysis buffer (50 mM tris; 50 mM EDTA; 1% SDS) and 20 mg/L Proteinase K solution. Plaques were incubated at 55 °C in shaking incubator for 1.5 hours. After incubation, plaques were washed with sterile ddH₂O two times and tris-EDTA (TE) buffer four times. TE and ddH₂O was held in water bath (55 °C) prior to washing. In each washing step, a filter was attached to tubes, then all liquid content was discarded, and replaced with ddH₂O and TE according to washing step. After fresh ddH₂O or buffer addition, tubes were incubated in a shaking incubator at 55 °C. After washing, plaques stored in TE solution at 4 °C. Next day, plaques were cut in 2mm sizes and placed in the agarose gel.

Plaques of reference strain were cut in 2 mm size, and placed into 1.5 mL centrifuge tubes. 200 μL H buffer (175 μL ddH₂O; 20 μL H buffer; 5 μL Xba1) was added, and the tubes were incubated for 10 minutes at 37 °C. After 10 minutes, H buffer was replaced with XbaI solution (175 μL ddH₂O; 20 μL H buffer; 5 μL Xba1) and incubated for 4 hours at 37 °C. 2.2 L running buffer (0.5% TBE) was loaded into PFGE tank and, the system was started in order to cool the buffer to 15 °C. After the incubation, plaques were loaded into 1.5% SKG agarose gel. Wells on the gel was

sealed with sealing agarose. Before the run, approximately, 1.5 mL thiourea solution was added to running buffer. The gel run in DNA-Chef DR III Biorad electrophoresis system with the conditions below (Table 3.8):

Table 3.8 Electrophoresis Conditions

| | |
|--------------------------|---------------------|
| DNA Size | 30 kb – 700 kb |
| % Agarose | % 1 |
| Voltage | 6.0 v/cm |
| Electrophoresis duration | 19 h |
| Angle | 120° |
| Initial Switch Time | 2.16s |
| Final Switch Time | 1.03 min 80 s |
| Pump Speed | 70 (0.75 L/minutes) |

After electrophoresis gels were stained with 10 mg/mL ethidium bromide solution for 45 minutes, and destained in distilled water for 30 minutes. Gel images were taken with Molecular Imager-Gel Doc-XR System Universal Hood II, and the software (PDQuest) provided by manufacturer. Band images were transferred to Bionumerics software. A dendogram showing genotypic clustering was drawn in Bionumerics, and band sizes of phages were estimated by using software tools.

3.14 Morphological analysis

Morphology of phages were determined in METU Central Laboratory by using high contrast transmission electron microscopy (CTEM). 10 phages were selected from our collection for TEM analysis (Table 3.9).

Table 3.9 Isolation data of selected phages for TEM analysis

Samples were prepared just before the analysis as described by Ackermann (2009). 1 mL of fresh and high titer phage stocks ($> 1 \times 10^8$) were transferred into centrifuge tubes, and centrifuged for 90 minutes at $21000 \times g$. Then supernatant was discarded, and replaced with 1 mL 0.1 M ammonium acetate solution. This step was repeated two more times. After that, 10 μ L sample was deposited on the TEM grid for phage adsorption. After 2 minutes, the droplet was taken carefully with a filter paper, and 10 μ L dye was added immediately. 2% sodium phosphotungstate was adjusted to pH 7.2 with 1 M NaOH, and was used as dye. After 2 minutes, remaining dye on the grid was removed with filter paper. Grids then allowed to air dry for 10 minutes, and then sent to METU Central laboratory immediately for examination. In Central Lab, images were taken with Tecnai T20 G² electron microscope operating at the accelerating voltage of 120 keV.

Phage morphologies were investigated in ImageJ image processor (Abràmoff et al., 2004). Head diameter for capsid size and tail size of each phage were measured at

least 30 times (Kuźmińska-Bajor et al., 2021). Averages and standard deviations (\pm SD) were calculated. Measurements were compared statistically by using student t-test. Shape and measurement of phages were compared to Ackermann's guide. This guide contains TEM images, measurements, and explanations of 177 *Salmonella* phages (Ackermann, 2007).

3.15 Bacterial reduction and virulence index

Effectiveness of phages against target bacteria was characterized by planktonic killing assay and virulence index (Haines et al., 2021; Storms et al., 2020). For this, mid-log culture was adjusted to 1×10^8 CFU/mL by using spectrophotometer ($OD_{600} = 0.1$). Also, fresh phage titers were prepared and titers were adjusted to 1×10^9 . 96 well plate was used for this analysis. In the first 4 wells of first column 180 μ L phage free bacteria added as control. In the last 4 columns, 180 μ L LB broth with colistin (512 mg/L) were added as blank. As a result, first column had control and blank only. 180 μ L bacteria was added to rest of the wells (Figure 3.3). Phage stock were diluted from 10^9 to 10^2 PFU/mL in eppendorf tubes, so that MOI of the wells ranged from 1 to 10^{-7} . Experiments were conducted with all the phage samples in triplicate. MULTISKAN SKY plate reader was used. Incubation temperature was set to 37 °C. For 24 hours OD (600nm) was measured for every 5 minutes. Plate was shaken for 5 seconds before each reading.

Figure 3.3 Plate setup for bacterial reduction curve. First 4 wells in the first column contains phage free DNA. Antibiotic added media was put in the last 4 wells as blank. Remaining wells contains bacteria plus phage solutions in decreasing MOI order (from 1 to 10^{-7}). Second, third and fourth wells belongs to cocktail 1, fifth, sixth and seventh wells belongs to cocktail 2, and eighth, ninth, and tenth wells belongs to cocktail 3.

Data was kept in the manufacturer software during the analysis, then were exported into Excel. Killing assay curves for each MOI were modeled with standard deviations based on the data. Virulence index was calculated from the area difference between the control (phage free bacteria) and each reduction curves by using the formula;

Equation 3.3
$$v_i = 1 - \frac{A_i}{A_0}$$

In the equation; V_i is the virulence index, A_i is the area of phage/ phage cocktail killing curve, and A_0 is the area of bacterial growth curve (Figure 3.4). Areas were calculated according to trapezoid rule.

Figure 3.4 Bacterial growth curves of control (A_0) and phage added bacteria (A_i)

3.16 Whole genome sequencing and bioinformatics

Whole genome sequencing was done commercially. Bacteriophages were analyzed in TEM were selected for whole genome sequencing (Table 3.9). DNA of the phages were extracted by Norgen Phage DNA isolation kit according to protocol provided by the manufacturer. Briefly, 10 mL fresh phage lysate with more than 1×10^8 PFU/mL titer was prepared for this analysis. 1 mL of the lysate were transferred into 15 mL falcon tube. Then DNase, lysis buffer, Proteinase K, and isopropanol were added, respectively. 650 μ L samples then were taken into spin columns that are attached to collection tubes. Tubes centrifuged for 1 min at $6000 \times g$. Flowthrough were discarded, and columns were washed with wash solution thrice with centrifugation in each step. After that columns were centrifuged at $14000 g$ for 2 minutes in order to dry the spin column thoroughly. Spin columns were attached to elution tubes, 75 μ L elution buffer was added to columns, and columns were spinned for 1 minutes at $6000 \times g$. A second elution step was performed in order to increase the yield. Purified DNA samples were stored at -20°C , and sent to service provider a day after. Samples were analyzed by Illumina NovaSeq platform.

Bioinformatics analyses of the samples were done in our lab. For the general pipeline, methods and software were mainly used as described in Shen & Millard, (2021) (Figure 3.5). Sequence files were obtained as raw reads (fq files). Quality check of raw reads were carried out by using FastQC (Storms et al., 2010). Trimmomatic (v 0.39) software was used to remove the Illumina adapters (Bolger et al., 2014). Since the phage genomes were short (e.g. 100kbp) a data reduction and subsampling were done in applied.

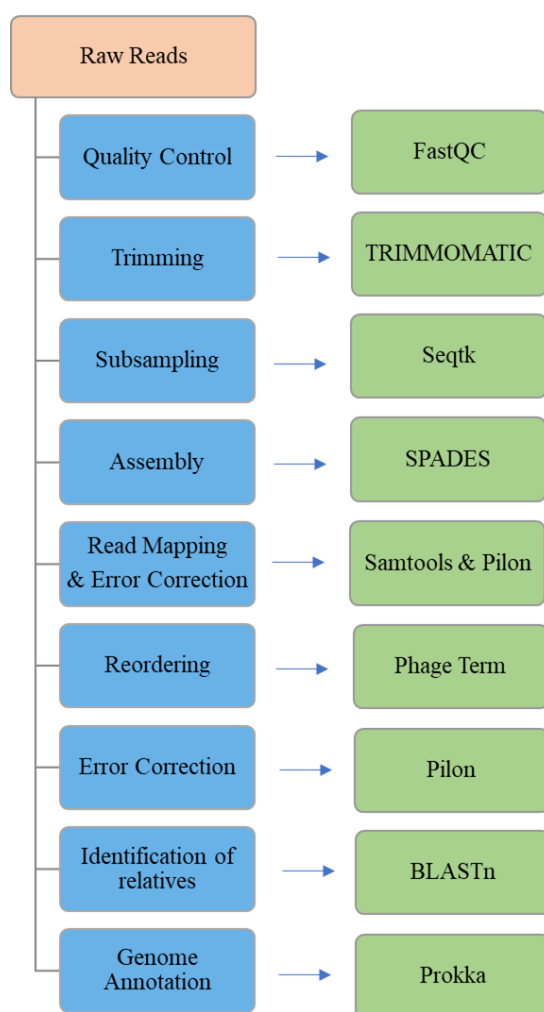

Figure 3.5 Workflow of analysis of phages from raw reads to annotation. Left column shows the analysis, and right column shows the tool. Pipeline was adapted from (Turner et al., 2021).

Phage genome assembly was done with SPAdes version 3.9.0 (Bankevich et al., 2012) by using default options, and assemblers were compared. Quality of assemblies, genome sizes and GC% contents was evaluated with QUAST (Gurevich et al., 2013). Assemblies graphs were first visualized by Bandage to ensure that there was no DNA contamination (Wick et al., 2015). After assembly, reads were mapped with bbmap.sh, as it gives the read coverage as default (Bushnell et al., 2019). Ideally, phage genome coverage should be between 20X and 200X (Shen & Millard, 2021). Based on the coverage scores, subsampling and assembly process were repeated. Assembly polishing and error correction was made by pilon (Walker et al., 2014). A preliminary check for closest relatives of assembled genomes were identified by BLASTn against Caudovirales database. Since the assemblers built genomes not in the correct order, a reordering step was applied to phage genome assemblies. Genomes from assemblies were reordered in two ways. First, all assemblies were assessed with PhageTerm (Garneau et al., 2017). PhageTerm is a software which predicts the genome packaging strategy and genome termini, and reorders the genome accordingly. For the assemblies that could be assessed by PhageTerm, reordered assembly produced by the software was used. For the phages that termini sites cannot be identified by PhageTerm, closest relative was identified (ANI > 90%). First 500 base pair of that relative was extracted with a python script, and aligned with the assembly in BLAST to determine the starting site. New assemblies then reordered (reversed, if necessary) with a python script according to alignment result. After reordering, all assemblies were assessed with pilon once again to ensure there were no errors.

Structural and functional annotations were done by Prokka (Seemann, 2014). Multiple genome alignments of phages were done in progressive Mauve (Darling et al., 2010). Taxonomic features (e.g. family, subfamily) were determined based on alignment scores the BLASTn. In addition, GRAViTy online tool was used to create a proteome based clustering by using DB-B: Baltimore Group I_b-Prokaryotic and archaeal dsDNA virus database (VMRv34) (Aiewsakun & Simmonds, 2018; Turner, Adriaenssens, et al., 2021). The dendrogram was visualized by using ITOL (Letunic

& Bork, 2019). Phylogenomic distance between the sequenced phages was evaluated by VICTOR (Meier-Kolthoff & Göker, 2017). Amino acid sequences were compared by pairwise comparisons using the Genome-BLAST Distance Phylogeny (GBDP) method (Meier-Kolthoff et al., 2014) with the settings proposed by Meier-Kolthoff & Göker (2017).

The resulting intergenomic distances were used to infer a balanced minimum evolution tree with branch support via FASTME including SPR postprocessing (Lefort et al., 2015) for each of the formulas D0, D4 and D6, respectively. Branch support was inferred from 100 pseudo-bootstrap replicates each. Trees were rooted at the midpoint (Farris, 1972) and visualized with FigTree (Rambaut, 2006).

Virulence genes were assessed by VFDB, the database provided by Liu et al. (2019). Antibiotic genes determinants in phage sequences were analyzed in ResFinder 4.1 with the default settings (Bortolaia et al., 2020).

3.17 *In vitro* phage application on feed

A crop assay was designed to test the ability of phages to reduce *Salmonella* Enteritidis and *Salmonella* Infantis in vitro as described by Andreatti Filho et al. (2007). In this assay MET P1-001, MET P1-100, MET P1-137, and MET P1-179 was tested. 500 g commercial poultry feed ration was obtained from retailer. Feed was autoclaved before the crop assay. Then 2 g of feed was weighted into sterile falcon tubes (50 mL). Concentrations of overnight *Salmonella* Enteritidis (MET S1-001) and Infantis (MET S1-006) cultures were adjusted to 1×10^8 by using a spectrophotometer (OD:0.1 at 600 nm). From that culture, two different concentrations, 8×10^6 and 8×10^3 , was prepared into 10 mL 0.9% NaCl solutions. 10 tubes containing 2g feed were prepared for each assay. In each tube, 5 mL 0.9% NaCl, 500 μ L adjusted *Salmonella* culture, and 1 mL 10^8 phage solution was added. 3 replicate tubes were prepared for each treatment. In addition, a control tube containing 1 mL 0.9% NaCl instead of phage solution was added for each test. All

of the tubes was vortexed 5 seconds in the beginning of the experiment, and incubated at room temperature (25 °C) at shaking incubator (150 rpm). Tubes were taken from incubator at 2. and 6. hour of experiment and vortexed for 5 seconds again. 100 µL of each tube was taken and plated onto XLD agar. Plates were incubated at 37 C for 24 hours, and colonies were counted. The data was processed in Excel. *Salmonella* levels for each treatment was plotted against control. In addition, means of treatment and control for each experiment was compared by student's t-test to determine if the difference between the means were significant.

CHAPTER 4

RESULTS AND DISCUSSION

4.1 Sample collection

In our study, 57 manure or wastewater sample were collected from various locations (Table 3.1). 53 of these samples were collected from farms, while 4 were taken from wastewater. Farm samples distribution was 55% poultry (29/53) to 45% cattle (24/53). 45 samples were collected in South Eastern Anatolia; 25 samples collected from Adiyaman, 20 samples were collected from Şanlıurfa (Figure 4.1). 5 Samples were collected from Bolu, 3 were collected from Denizli, and 4 collected in Ankara (Figure 4.2).

Figure 4.1 Location of farms in Adiyaman and Şanlıurfa.

Figure 4.2 Location of farms in Bolu and Denizli, location of wastewater facility in Ankara

24 of the samples were collected in summer, 22 were obtained in autumn, and 11 samples were collected in winter. Due to COVID precautions no sampling made in spring season. *Salmonella* and bacteriophage isolation were conducted synchronously from the samples.

4.2 Isolation of *Salmonella*

In our study, 12 *Salmonella* were isolated from a total of 57 samples (Table 4.1). Isolated colonies were confirmed by PCR amplification of *invA* gene (Figure 4.3). Isolation of *Salmonella* were not distributed homogenously between isolation dates and locations. For example, all 3 farm samples from Denizli were *Salmonella* positive, whereas *Salmonella* couldn't be isolated from Bolu samples. Moreover, more than half of the *Salmonella* isolation (7/12) was conducted from November samples. On the other hand, prevalence in February, August, and October samples were 0. Similarly, all isolation was made from farm samples, whereas all wastewater samples were

Salmonella free. Even the farm samples showed non-homogenous distribution. While 55 % of samples were collected from poultry farms, 75 % (9/12) of isolated *Salmonella* came from poultry farms. On the other hand, only 3 *Salmonella* were able to be isolated from 24 cattle samples.

Table 4.1 *Salmonella* isolation from farm samples

| METUID | Genus | Serotype | Source | Isolation Date | City |
|---------------|-------------------|-----------------|---------------|-----------------------|-------------|
| MET A2-188 | <i>Salmonella</i> | Anatum | Poultry Farm | 29/06/2020 | Şanlıurfa |
| MET A2-191 | <i>Salmonella</i> | Infantis | Poultry Farm | 29/06/2020 | Denizli |
| MET A2-194 | <i>Salmonella</i> | Infantis | Poultry Farm | 29/06/2020 | Denizli |
| MET A2-197 | <i>Salmonella</i> | - | Poultry Farm | 29/06/2020 | Denizli |
| MET A2-200 | <i>Salmonella</i> | Kentucky | Poultry Farm | 25/09/2020 | Şanlıurfa |
| MET A2-209 | <i>Salmonella</i> | Montevideo | Cattle Farm | 19/11/2020 | Şanlıurfa |
| MET A2-212 | <i>Salmonella</i> | Kentucky | Poultry Farm | 19/11/2020 | Şanlıurfa |
| MET A2-215 | <i>Salmonella</i> | Typhimurium | Poultry Farm | 19/11/2020 | Şanlıurfa |
| MET A2-218 | <i>Salmonella</i> | Mikawasima | Poultry Farm | 19/11/2020 | Şanlıurfa |
| MET A2-221 | <i>Salmonella</i> | Kentucky | Cattle Farm | 19/11/2020 | Adiyaman |
| MET A2-224 | <i>Salmonella</i> | - | Cattle Farm | 19/11/2020 | Adiyaman |
| MET A2-227 | <i>Salmonella</i> | - | Poultry Farm | 19/11/2020 | Şanlıurfa |

All in all, *Salmonella* prevalence 31% and 12.5% in poultry manure and cattle manure, respectively. Our findings were comparable with Gıda ve Kontrol Genel Müdürlüğü's report. In that report *Salmonella* prevalence was found 24% in broiler chicken, and 47% in chicken carcasses (Gıda ve Kontrol Genel Müdürlüğü, 2018). However, our results indicate that *Salmonella* prevalence in poultry was much higher than the EU average, which was 3.9% in 2020 and 3.6% in 2019 (EFSA, 2021).

Figure 4.3 PCR gel image for *invA* (389 bp) gene. L: Ladder (100 bp), +: positive control (MET S1-001), -: negative control, 1-12: samples collected in June.

In literature, there are contradictory reports regarding the prevalence of *Salmonella* in poultry and poultry products. In a study, *Salmonella* prevalence in broiler flocks from Southeastern Anatolia, Marmara and Black Sea regions was reported as 15.6% (Yapicier & Sareyyupoglu, 2022). In another study conducted in Eastern Anatolia region, *Salmonella* prevalence in poultry was higher than 80% (Arkali & Çetinkaya, 2020). Siriken et al. (2015) reported prevalence of *Salmonella* in chicken meat was 42.6%. In another study, *Salmonella* prevalence in samples from ground meat and meatballs were 20% (Siriken et al., 2020). All these results show that a more comprehensive and regular monitoring should be conducted in each region.

4.3 Genomic characterization of *Salmonella* isolates

Genomic characterization of isolates was done by PFGE, which was the gold standard for bacterial subtyping until the emergence of whole genome sequence analysis, due to its discriminatory power (Neoh et al., 2019). PFGE gel pictures were presented in Appendix I.

PFGE patterns are also useful for serotype estimation of *Salmonella* isolates. After clustering analysis, patterns can be compared with an existing database of PFGE patterns for serotyping (Gaul et al., 2007). In addition to accurate estimation of serotype,

PFGE also offers less labor intensive, rapid, and cheaper way compared to traditional methods (Zou et al., 2010). Therefore, *Salmonella* serotypes were determined based on their PFGE patterns. For this, our PFGE database was used for comparison. 9 of the samples were able to be serotyped with PFGE (Figure 4.4). 3 isolates were serotyped as Kentucky, and 2 isolates were determined as Infantis, both of which were amongst the most prevalent serovars in Turkey. From the other serotypes, we found a Typhimurium, Anatum, Montevideo, and a Mikawasima, while the former 3 serotypes are also common, Mikawasima is a relatively rare serotype. Clustering analysis showed that Infantis isolates showed the same band pattern. Those isolated also showed same antibiotic resistance profile. Considering the fact that those isolates recovered from different farms in Denizli, there might be a clonal dissemination of multidrug resistant Infantis strain in Denizli region.

Figure 4.4 Cluster analysis of *Salmonella* isolates

Clustering analysis also revealed serotype based clustering (Figure 4.4). Date, source, and location was not found relevant in clustering. However, this might be due to the small sample size.

4.4 Antibiotic resistance characterization of *Salmonella* isolates

All isolates were tested with disk diffusion method (Table 4.2). Disk diameters (mm) were given in Appendix A. Only 2 isolates (MET A2-188 and MET A2-209) were found susceptible to antibiotics. In addition, 2 isolates (MET A2-197 and MET A2-218) were resistant to streptomycin. Remaining isolates (8/12) showed multidrug resistance. Among those, 5 isolates showed resistance to fluoroquinolone class (ciprofloxacin and

pefloxacin). Fluoroquinolones are clinically important drugs for the treatment of Gram negative infections including *Salmonella*, which are considered as first line of treatment with third generation cephalosporins (WHO, 2020). In addition, 6 isolates showed resistance against ampicillin, another important drug from penicillin class that was used against salmonellosis, previously.

Table 4.2 Antibiotic resistance profiles and antibiotic genes of *Salmonella* isolates

| Serotype | Source | METUI D | City | Resistance Profile | AR Genes |
|-------------|--------------|------------|-----------|------------------------|-----------------------------|
| Anatum | Poultry Farm | MET A2-188 | Şanlıurfa | Susceptible | - |
| Infantis | Poultry Farm | MET A2-191 | Denizli | SPefNTeSxtSf | <i>parC tetA sulI</i> |
| Infantis | Poultry Farm | MET A2-194 | Denizli | SPefNTeSxtSf | <i>parC tetA aadA1 sulI</i> |
| - | Poultry Farm | MET A2-197 | Denizli | S | <i>parC aadA1</i> |
| Kentucky | Poultry Farm | MET A2-200 | Şanlıurfa | CnSAmpKfAmcPefNTeSfCip | <i>parC tetA strB sulI</i> |
| Montevideo | Cattle Farm | MET A2-209 | Şanlıurfa | Susceptible | |
| Kentucky | Poultry Farm | MET A2-212 | Şanlıurfa | CnSAmpPefNTeSfCip | <i>tetA sulI</i> |
| Typhimurium | Poultry Farm | MET A2-215 | Şanlıurfa | AmpCPefNTe | <i>qnrB qnrS</i> |

| - | Cattle Farm | MET A2-224 | Adiyaman | AmpFoxKfAmc | - |
| - | Poultry Farm | MET A2-227 | Şanlıurfa | SAmcFoxKfAmcTeSf | <i>tetA sulI</i> |

Sf: Sulfisoxazole, Sxt: sulfamethoxazole-trimethoprim, Ak: Amikacin, Cn: Gentamicin, K: Kanamycin, S: Streptomycin, Cip: Ciprofloxacin, N: Nalidixic Acid, Amp: Ampicillin, Amc: Amoxicillin-clavulanic acid, T: Tetracycline, Fox: Cefoxitin, Kf: Cephalotin, Pef: Pefloxacin

Comparison of resistance profiles revealed that 2 Infantis isolates showed identical resistance. A similar pattern was observed for MET A2-221 and MET A2-224 both of which were isolated from a cattle farm in Adiyaman. Two Kentucky isolates from poultry farms showed resistance against 8 and 10 drugs. This might explain the high prevalence of Kentucky serotype in poultry. Although Kentucky is rarely associated with human salmonellosis cases spread of antibiotic resistance is still a threatening

issue. Resistance genes might spread interspecies on mobile genetic elements through horizontal gene transfer (Arnold et al., 2021).

Screening of AR genes revealed *qnrB* and *qnrS* genes in Typhimurium (MET A2-215). These genes are responsible from plasmid mediated quinolone resistance, and linked with the rapid spread of quinolone resistance globally (Lin et al., 2015). In addition, 4 isolates had chromosomal mutations in topoisomerase IV *parC* region, which is often associated with elevated resistance levels against fluoroquinolones (Pribul et al., 2016). In some instances, mechanism of phenotypic resistance couldn't be determined genotypically. This was due to the fact that there are multiple mechanisms that might confer resistance. For example, there are over 1100 β -lactamase genes known to confer resistance against β -lactam class antibiotics (McDermott et al., 2018). Similarly, many different aminoglycoside and fluoroquinolone resistance mechanisms were reported. Screening all of these mechanisms would not be feasible. With the rapid advances in technology, *in silico* determination of the mechanisms through whole genome sequencing is available. Combining sequencing data with lab screening would be the most reliable determination of resistance (Carroll et al., 2017). However, the cost of whole genome sequencing is still high for routine screening.

Our findings were also in agreement with our previous studies. Durul et al. (2015) reported high resistance rates among the *Salmonella* isolated from various foods in Şanlıurfa region. Similarly, Acar et al. (2017) reported very high resistance rates among *S. Infantis* isolates.

4.5 Isolation and titer determination of bacteriophages

In this study, 68 phages targeting different *Salmonella* serotypes were isolated from 53 farm and 4 wastewater samples. While some hosts (Kentucky, Anatum, Montevideo, Telaviv, Hadar) were used only in wastewater samples, Enteritidis, Typhimurium, and Infantis were used in all 57 samples, as they are determined as the most clinically relevant serotypes. According to Gıda ve Kontrol Genel Müdürlüğü's report, more than 80% of clinical *Salmonella* isolates were belong to those 3 serotypes (Gıda ve Kontrol Genel Müdürlüğü, 2018). This was also the case in the EU. Most isolated clinical

isolates in the EU were Enteritidis, Typhimurium and its monophasic variant, and Infantis (EFSA, 2021). In addition, using all 8 hosts in farm samples would not be feasible as farm samples were obtained in batches (5 samples per location, per month).

Phage isolation rates in summer, autumn and winter were 62%, 131%, and 114%, respectively (Figure 4.5, Figure 4.6, Figure 4.7). After our study, Deniz (2022) collected samples in Spring season, reported phage isolate 90%. There was no relationship between the seasons and isolation rates. In our study, wastewater samples were collected in August, October, November, and December. Using more hosts for wastewater samples, caused an apparent increase in isolation rates.

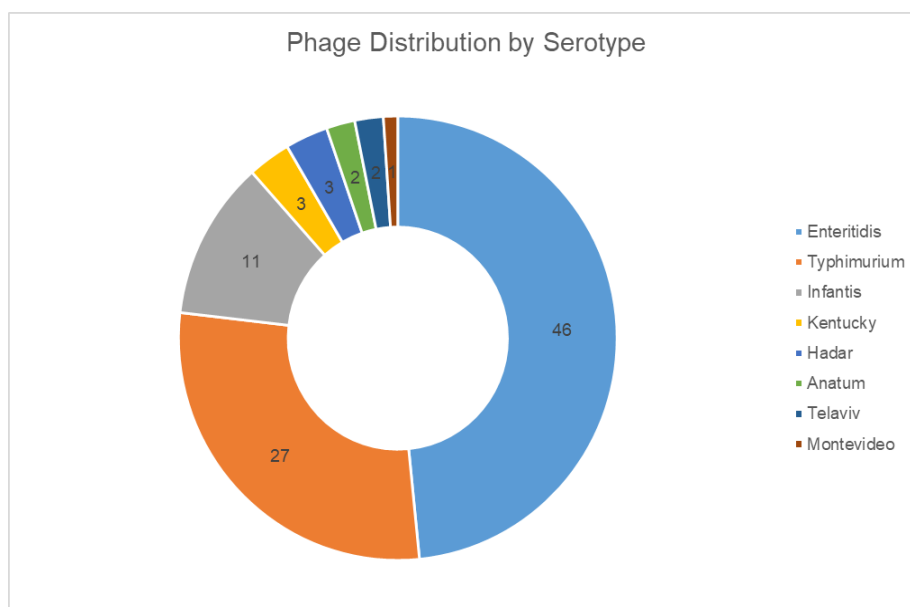

Figure 4.5 Pie chart of isolated phage distribution by serotype.

Enteritidis, Typhimurium, and Infantis were used as host in all 57 sample. Therefore, comparing the phages that belong to those 3 hosts might be a better idea. In that case, overall Enteritidis phage isolation rate was 80% (46/57), and isolation rate from farms only was 83% (44/53). A similar, small increase were observed for Typhimurium as well; isolation rate was 47% and 49%, for overall and farm only isolation rates. However, isolation rate of Infantis phages in farms (13%) were lower than overall

isolation rate (19%). This is due to the fact that in Infantis phages were abundant in wastewater, and unlike Enteritidis and Typhimurium, at least one Infantis phage were isolated from wastewater samples. However, Infantis phage prevalence were significantly lower than Enteritidis and Typhimurium. This was particularly interesting because in separate studies prevalence of Infantis in poultry were reported higher than Enteritidis and Typhimurium (Durul et al., 2015; Gıda ve Kontrol Genel Müdürlüğü, 2018). During the isolation a notable month was December in which we collected sample from METU wastewater facility. From that sample we were able to isolate one phage for each host; Enteritidis, Typhimurium, Infantis, Kentucky, Montevideo, Telaviv, Hadar, and Anatum. However, during the isolation it is impossible to decide if all the phages were unique, or the same phage that were able to infect all the hosts.

Figure 4.6 Bar chart shows how many samples were taken, and how many phages were isolated monthly

In a similar study, Yildirim et al. (2018) isolated 33 Typhimurium and 56 Enteritidis phages from 92 wastewater samples. Their isolation rates were 35% and 60% for Typhimurium and Enteritidis, and were comparable to ours.

Figure 4.7 Seasonal changes in phage isolation. Bar chart shows how many samples were taken, and how many phages were isolated in that season.

After isolation, phages purified with a 3 step purification process because in some samples there were several different phage plaques (Figure 4.8). These steps were necessary to obtain single phages.

Figure 4.8 Different plaque formations observed in petri plates.

After purification, phages were stored according to the scheme (Figure 3.1). Before storage, a unique identifier (METU ID) was assigned each phage (Table 4.3). Since

each phage were stored in triplicate, a phage databank was created containing 204 entries (68 x 3). Whole table was given in Appendix B.

Figure 4.9 Sample phage photos; left: MET P1-100 (Infantis), right: MET P1-137 (Kentucky)

In general, Enteritidis and Typhimurium phages produced bigger plaques than the rest Figure 4.9 and Figure 4.10. Phage plaque size is dependent of phage intrinsic characteristics and environmental determinants (i.e. agar density, time, and host concentration) (Abedon & Yin, 2009). Since extrinsic factors such as agar density and time were equal, intrinsic factors might determine the plaque size. Gallet et al. (2011) found that phage concentration and lysis time relationship, virion morphology and adsorption rate affects the plaque size. In addition, phage diffusivity, latent period and burst size were also found effective on plaque size (Abedon & Yin, 2009).

Several phages showed depolymerase activity (Figure 4.10). These phage plaques had an outer zone that more faint than actual plaque zone. This zone is called as translucent halo, and means that phage produces a depolymerase enzyme (Lai et al., 2016). Phage tail proteins, tail spike and tail fiber, were reportedly show depolymerase activity (Yan et al., 2014). The depolymerase enzyme might diffuse further than phage itself due to its smaller size, and might degrade exopolysaccharides of host. This enzyme had a lot

of potential in a number of biomedical applications such as biofilm removal and antibiotic adjuvant (Pires et al., 2016). The polymerase activity was specifically observed in Enteritidis phages.

Figure 4.10 Phage depolymerase activity. Phage on the left (P1-103) showed polymerase activity (outer halo) whereas phage on the right (P1-122) did not.

Characterization of phages has started in January 2021 with titer determination of phage stocks. Phage titers are indicators of stock efficiency. Since some of the phages were frozen more than a year ago, titers had to be determined to check if there was a drop in phage titers. Also, phage titers need to be adjusted for further characterization steps. For example, in host-range determination analysis, phage titers should be at least 1×10^8 . As a result, titers of all phages were determined before further characterization (Appendix C). All of the phages titers were higher than 1×10^8 . Furthermore, more than half of the phages had titers above 10^{11} . Significant drops in phage titers were not observed. The results showed that concentration of phages was not affected by storage at 4°C .

Table 4.3 Sample phage databank entry which contains general phage isolation information

| METUID | PreviousID | Genus | Serotype | Titer (PFU/mL) | Verified By | Source General | Source Specific | Keywords | Month | Year | Exact Date | City | Country |

4.6 Bacteriophage lysis profiles on different hosts

Host range determination of bacteriophages were determined 36 isolates representing 18 serotypes given in Table 3.7. Complete table of interactions were given in Appendix D. A sample figure was presented in Figure 4.11. 66 of 68 phages were able to partly or completely lysed 10 or more hosts. Furthermore, 19 phages lysed 20 or more hosts. Most efficient phages based on the host range were P1-091, P1-094 and P1-125; these phages lysed 27, 28, and 27 different hosts respectively. P1-091 and 094 were isolated in October from Adiyaman samples by using *Infantis* as target host. P1-091 was isolated from cattle farm sample while P1-094 was isolated from poultry farm sample. P1-125 was isolated same month from wastewater sample by using *Kentucky* as target host.

Figure 4.11 Host ranges of phages P1-073 to P1-094 against the A2-012 (*Enteritidis*) and A2-072 (*Kentucky*)

On average, phages were lysed 16 different hosts (Figure 4.12). While a phage completely lysed 7 of 36 hosts, partly lysed 9. On average, phages were ineffective against 19 hosts. There was no apparent relationship between host-range and isolation date or location. Isolation location was found effective on phage host range on a larger scale. Wongsuntornpoj et al. (2014), reported that phages isolated in Thailand shoed broader host range than isolated in the US.

Figure 4.12 Bar graph of phage effectiveness.

While phages isolated from farms lysed 15 hosts in average, wastewater phages lysed 19 hosts (Figure 4.13). The results suggested that the host-range of wastewater phages are more diverse and broader than the farm phages. This result might be due to the fact that wastewater consist a vast variety of sources such as human, animal, and environmental, the phages in wastewater were evolved to infect more serotypes than the farm counterparts. Indeed, broader host range of wastewater phages compared to manure was reported (Akhtar et al., 2014). In another study, Parmar et al. (2018) suggested that since wastewater microflora is more distinct and changes frequently, host range of phages from wastewaters were expected to be broader. On the other hand, since farms have predominant serotypes, phages from farms were not able to diverse set of bacteria.

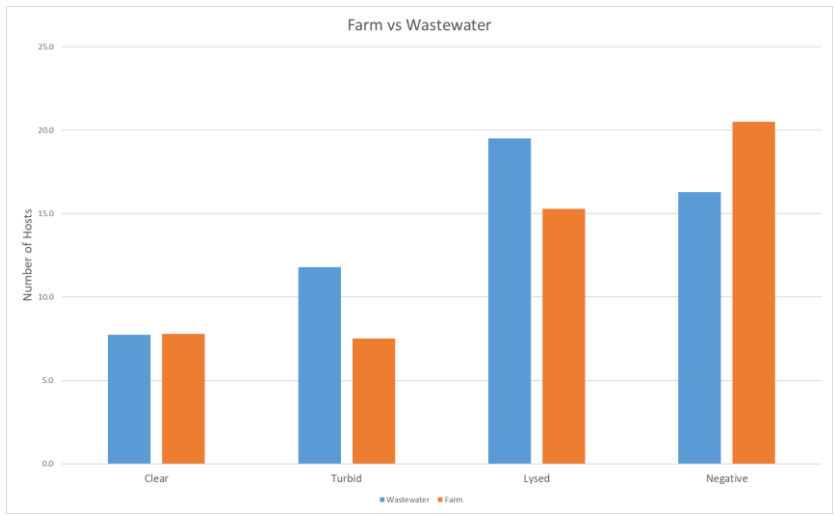

Figure 4.13 Comparison of the effectiveness of phages isolated from farm and wastewater.

In addition to most prevalent non-typhoidal serotypes, we also tested 2 human pathogens *Salmonella* Typhi and *Salmonella* Paratyphi B. Only 2 phages were not able to lyse Paratyphi B, 66 phages lysed the target partly or completely. Conversely, Typhi was much less effected from the phages. 8 phages lysed Typhi, while only 3 of those completely lysed the bacteria. All in all, the results showed the therapeutic potential of phages.

Figure 4.14 Effect of different phages on *Salmonella* Paratyphi B. 61 phages were able to lyse Paratyphi B.

As stated in 3.6, phage-host interactions were graded based on the interaction type, from complete clearing to no interaction. Based on those interactions, a heat map was built in R software (Figure 4.15). In the heatmap, darker colors indicated strong interaction. In general, isolates from Typhimurium and Enteritidis serotypes were affected from same set of phages. Phages that were isolated using Enteritidis and Typhimurium affected both serotypes. However, other phages were not very effective against these serotypes. Similarly, while Enteritidis and Typhimurium phages were generally ineffective against Infantis, other phages successfully interacted with Infantis.

Figure 4.15 Heatmap showing phage-host interactions. Darker colors (red) indicate a strong lytic activity whereas light colors mean no interaction.

Based on their interactions with their hosts phages were clustered in R by using Ward's method (Figure 4.16). This hierarchical clustering method classified phages in 2 large branches, both of which divided into further subgroups. Also, a cluster plot was drawn based on Ward's method. As expected, phages were clustered according to their hosts. For example, almost all of the Enteritidis and Typhimurium phages were presented in two neighbor branches, while the others were in the other major branch, with several exceptions. For example, MET P1-131, an Enteritidis phage, was clustered with Hadar and Anatum phages. More intriguingly, 2 Typhimurium, 2 Infantis, 1 Enteritidis, Anatum and Kentucky phages were clustered together. More interestingly, there were no apparent relation among these phages. For instance, one of the Typhimurium phages was isolated from wastewater in December, while the other was isolated from cattle farm in November. Moreover, one of the two phages were isolated from samples from Sanliurfa in September, while the other was recovered from Adiyaman samples in November. However, other than that branch, other phages were clustered expectedly. In fact, several phages showed exact same profile, namely MET P1-013 and MET P1-016, MET P1-037 and MET P1-040, and MET P1-073 and MET P1-076. All of these same profile showing phages came from same farms in same month. They were either isolated by different hosts (Enteritidis and Typhimurium) or showed different morphologies. However, based on their host range analysis, they were most likely same phages.

Figure 4.16 Phage clustering by Ward's method.

Host range analysis is a good method for clustering the *Salmonella* isolates as well. Historically, phage typing is an important phenotypic sub typing method for *Salmonella* (Callow, 1959; Ward et al., 1987). Phage typing lost a lot of interest with the emergence of molecular subtyping methods with much more resolution (Crabb et al., 2019).

However, it might be still useful in epidemiological studies with a well-defined set of phages (Baggesen et al., 2010). In our study, hosts were clustered with Ward's method like phages (Figure 4.17).

Figure 4.17 Clustering of 36 *Salmonella* isolates based on their phage interactions.

Isolates were grouped under 2 major branches. While the upper branch mostly consisting the Enteritidis and Typhimurium isolates, lower branches were more heterogeneous. Similar to phages, isolates were clustered expectedly and consistent

with their serotypes, with a few exceptions. For example, 3 Infantis isolates were presented in different nodes. This might be a feature of Infantis serotype. Pardo-Este et al. (2021) reported that very diverse Infantis strains might present in poultry farms. Isolates in the upper branch were mostly susceptible to phage infections. For example, Paratyphi B were infected by 61 phages, and Virchow were infected by 57.

Another different response to phages was observed in Anatum isolates (Figure 4.18). Although both isolates were isolated in same day from food sources, and they had same PFGE profiles, their phage susceptibility were different. As shown in Figure 4.18, while S1-548 was infected by Infantis phages (P1-091 and P1-094), S1-579 lysed by Hadar phages (P1-085 and P1-088). All in all, S1-579 showed resistance against 51 phages while S1-548 was unaffected by 39. Another different isolate was MET S1-217, a clinical Enteritidis isolate. That Enteritidis isolate were resisted nearly all Enteritidis phages, while lysed by Infantis, Hadar, and Anatum phages. That was not observed in any other isolate.

Figure 4.18 Host ranges of phages P1-073 to P1-094 against the S1-548 (Anatum) and S1-579 (Anatum).

In four isolates, namely Hadar, Braenderup, Mbandaka, and Liverpool, unusually high phage resistance observed (Figure 4.19). Braenderup resisted 60 phages, Liverpool resisted 62, and Mbandaka resisted 65 phages. Furthermore, Mbandaka isolate couldn't

be fully lysed by any of the phages. Also, Hadar isolate resisted 59 phages. In addition, 3 of the 7 phages that infected Hadar, were Hadar phages. Apart from Braenderup, all 3 serotypes were among the most prevalent serotypes in poultry (Gida ve Kontrol Genel Mudurlugu, 2018). In addition, Braenderup recently caused outbreaks, one associated with eggs in the US (Garcia et al., 2022) and another one associated with melons in the EU (EFSA, 2021).

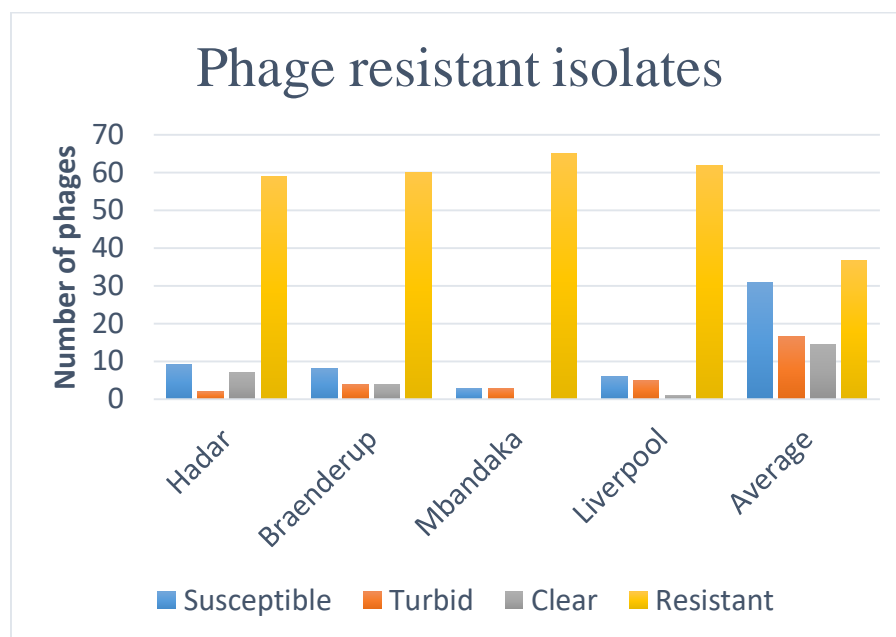

Figure 4.19 Phage resistant isolates, and average resistance rates of all isolates.

Based on the host interactions, 10 phages were chosen for further characterization experiments (Table 3.9). These phages were also tested against *E. coli* O104:H4 and *E. coli* O157:H7. While none of the phages was effective against O104:H4, one phage (MET P1-179) was able to produce a clear plaque by lysing O157:H7 (Figure 4.20).

Figure 4.20 Host range analysis of selected phages against *E. coli* O157:H7 (MET K1-30).

4.7 One-step growth curves, latent periods and burst sizes

One-step growth curve, latent period, and burst size of selected phages were determined for selected phages (Figure 4.21, Figure 4.22, Figure 4.23, Figure 4.24, Figure 4.25, Figure 4.26, Figure 4.27). 2 different Infantis phages (P1-116 and P1-179) were characterized due to genomic differences. P1-179 had a different genome than rest of the Infantis phages, and closer to Kentucky phage (P1-137). Although sigmoidal growth curves are used to describe bacterial growth, Gompertz model was fitted into model with a high R^2 value ($R^2: > 0.92$ for all phages). This model was found useful for latent period and burst size determinations as well. Latent period of the phage was determined as from the graphs, and burst sizes were calculated (Table 4.4).

MET P1-197

Figure 4.27 One step growth graph of MET P1-197. This phage was the representative of Anatum phages.

Table 4.4 Latent period and burst sizes of selected phages

| Phage ID | Host | Latent Period (min) | Burst Size (PFU/cell) |
|------------|--------------------------|---------------------|-----------------------|
| MET P1-001 | Enteritidis, Typhimurium | 36 | 120 |
| MET P1-164 | Enteritidis, Typhimurium | 30 | 42 |
| MET P1-088 | Hadar | 66 | 47 |
| MET P1-137 | Kentucky | 66 | 18 |
| MET P1-197 | Anatum | 54 | 110 |
| MET P1-116 | Infantis | 72 | 21 |
| MET P1-179 | Infantis | 60 | 16 |

Phages that affecting different hosts showed different characteristics with some exceptions. Kentucky and Infantis phages were exhibited very similar burst sizes and latent periods. Considering the fact that these phages were very closely related genomes, the results were found consistent with whole genome analysis. In fact, one of the Infantis phages (P1-179) were had a closer phylogeny to Kentucky phage (P1-137). Their phenotypic characteristics were also almost identical, while showing a small variation to other Infantis phage (P1-116). Based on the results, MET P1-001 showed the best burst size – latent period combination. Anatum phage P1-197 had a similar burst size, but a longer latent period than P1-001. After these two phages, Hadar phage P1-088 had a considerably longer latent time and smaller burst size. However, burst sizes Infantis and Kentucky were about 6 times less than P1-001, while latent period was nearly 2 times longer.

In literature, there are a wide variety of reports present. For example, latent period and burst size of a Chi-like phage was determined by Choi et al. (2013). Latent period of that phage was 30 minutes, and burst size was 100 PFU/infected cell, both of which were close to our findings for P1-001. However, in another study with Chi like phages, latent period was found 60 minutes and burst size was 48 PFU/infected cell (Phothaworn et al., 2019). In a study, phenotypic characteristics of 5 Jerseyvirus were determined (Kuźmińska-Bajor et al., 2021). Although the phages had very similar genomes, burst sizes varied from 23 PFU/cell to 201 PFU/cell. In addition, latent periods of phages were in between 9 and 24 minutes. The results indicated that the functional characteristics are not directly associated with genomic features (Kuźmińska-Bajor et al., 2021).

The relationship between latent period and burst size was reported inconclusive and weak (Ranasinghe, 2019). As a rule of thumb, shorter latent periods and higher burst sizes are favorable in phage applications. In a study, Li et al. (2021) reported a *Salmonella* phage with 10-minute latent period and 163 PFU/infected cell, and describe that phage as a viable candidate for phage application. However, in another study, Zhang described their *Salmonella* phages latent period as 20 minutes and burst size 34 PFU/infected cell. In that study, authors also speculated that the phage was a promising

biocontrol agent due to short latent period (Zhang et al., 2021). Although these characteristics might be useful to evaluate the phage effectiveness, candidate phages should be tested in designated application conditions such as food or feed matrix.

4.8 Adsorption rates

Adsorption rates of selected phages were determined (Figure 4.28, Figure 4.29 Figure 4.30, Figure 4.31, Figure 4.32, Figure 4.33, and Figure 4.34). All the graphs were drawn in Sigmaplot.

Figure 4.28 Adsorption rate of MET P1-001 (Enteritidis, Typhimurium)

MET P1-137

Figure 4.33 Adsorption rate of MET P1-137 (Kentucky)

MET P1-197

Figure 4.34 Adsorption rate of MET P1-197 (Anatum)

Adsorption rate is an important feature for phage applications for food protection (Kosznik-Kwaśnicka et al., 2020). In our study, Hadar phage showed the best adsorption rate among the tested phages with 0.4% free phage at 10 minute (Table 4.5). Indeed, free phage % were dropped below 1 % at 5 minute. Anatum and Enteritidis phages had 2.3 and 4.2 free phage % at 10 minutes, respectively. However, adsorption rate of the other Enteritidis phage (P1-164) were less than 87%. In general, Infantis and Kentucky phages showed similar performances. Moreover, similar to one step growth analysis, results of P1-179 and P1-137 were closer than P1-179 and P1-116. In a study, adsorption rates of 5 closely related phages were determined. Although genomes of those phages showed 99% similarity, adsorption rates varied from 1 % free phage to 20 % free phage (Kuźmińska-Bajor et al., 2021).

Table 4.5 Adsorption constants and free phage % at 10 minute

| Phage ID | Host | Free phage (%) | Adsorption Constant (k) |
|------------|-----------------------------|----------------|-------------------------|
| MET P1-001 | Enteritidis, Typhimurium | 4.2 | 8.46×10^{-7} |
| MET P1-164 | Enteritidis, Typhimurium | 13.2 | 7.31×10^{-7} |
| MET P1-088 | Hadar | 0.4 | 1.08×10^{-7} |
| MET P1-137 | Kentucky | 9.6 | 7.63×10^{-7} |
| MET P1-197 | Anatum | 2.3 | 9.06×10^{-7} |
| MET P1-116 | Infantis | 6.2 | 8.07×10^{-7} |
| MET P1-179 | Infantis | 11.1 | 7.5×10^{-7} |

4.9 Genome size estimation

Fresh high titer phages were entrapped into SKG agarose gels and their genome size were investigated. All PFGE gel pictures were presented in Appendix I. Most of the phage genomes couldn't be visualized on gels (Figure 4.35). Analysis were repeated with high titer phage lysates, and also different phages. However, the problem persisted, especially for Enteritidis phages. All in all, bands were observed for 5 different phages.

In some cases, multiple bands (one bright and one faded) were observed (Figure 4.35). These bands were considered as ghost bands due to phage DNA degradation during the plaque preparation. However, these bands might as well be resulted from a contamination of another phage. (Gao et al., 2020). investigated the comparative genomics of *Salmonella* prophages. In that study, majority of the prophages had between 30 to 50 kb genomes. The faint bands in our study were also found in that size range. Therefore, some of those phages (P1-001, P1-122) were further investigated with whole genome sequencing.

Figure 4.35 Cluster analysis of phages.

In one phage (P1-100), two sharp bands were observed. Later in genome analysis, it was seen that there were actually two different phages in P1-100. For another phage, P1-103, we initially observed two bands, one bright and one faded. In another PFGE run, this phage exhibited a band at 240 kb region. This phage was also selected for sequencing as well.

Phage gels were investigated in Bionumerics for band size (Figure 4.36). In our phage PFGE database, we have a total of 26 phage genomes (19 from this study). A dendrogram created based on the genome size. However, it should be noted that dendrogram was

based on a single band. As a result, it was inconclusive in terms of genetic relationships of phages. For instance, if two phages produced bands in different sizes, they could be appointed as different phages. However, same conclusion couldn't be made for phages with similar band sizes.

Figure 4.36 Band size estimation of phages by Bionumerics. Phages P1-209, P1-230, P1-235, P1-238, P1-239, P1-264, and P1-276 belongs to another study.

In general, phages that target same serovar produced bands in similar sizes with a few exceptions (Table 4.6). Bands sizes of 8 Enteritidis phages clustered in 3 groups; 5 phages had bands around 55 kb, 2 phages had 35 kb bands, and 1 phage with 240 kb band. There was no apparent relationship between the band size and isolation date or region. 3 Hadar phages had bands around 120 kb. Similar size region was also observed in Infantis and Anatum phages. Kentucky phage was similar to one of the Enteritidis clusters with 55 kb size. Typhimurium phage was also similar to one of the Enteritidis clusters with 35 kb.

Table 4.6 Band sizes of typed phages

| Phage | Host Serotype | Isolation Date | Band Size (kb) |
|--------------|----------------------|-----------------------|-----------------------|
| P1-001 | Enteritidis | 10.02.2020 | 51 |

Although PFGE provided only genome sizes, we could associate the data with literature to make assumptions on phage families. For this, Infrastructure for a Phage Reference Database (INPHARED) was used (Cook et al., 2021). This database contains 556 *Salmonella* phage genome uploaded to NCBI database. Although *Salmonella* phage genomes varies from 11 kbp to 350 kbp, there were some distinguishable clusters. For example, all 30 phage genomes with 240 kbp size were identified as *Myoviridae* family. In addition, all 30 phages were lytic. Most of our phages were in between 110 to 120 kbp range. There were 104 phages in INPHARED in that genome size range. All of those phages were from *Demerecviridae* family. While majority of those phages were identified as Epseptimavirus, a small portion were from Tequintavirus family. Similarly, all 104 phages in that range were lytic phages (Cook et al., 2021). For other ranges, genome sizes of database entries were highly diverse, thus linking our phages to families based on genome size were impossible.

4.10 Morphological analysis

Phage morphology was investigated by CTEM images. 10 phages were prepared and stained for TEM and images were taken by Central Laboratory (Figure 4.37, Figure 4.38, Figure 4.39, Figure 4.40, Figure 4.41). Images of a phage (MET P1-091) was unsatisfactory. Rest of the images were processed with ImageJ software, and head and tail measurements were recorded (Table 4.7). Means of measurements were analyzed by student's t-test, to determine if the difference between the measurements were significant. In total, 18 different phages with different measurements were identified in 10 phage lysate image ($p < 0.05$). In terms of measurements, in 5 of the images, there were two distinct phages, and images belong to P1-164 and P1-179 had single phage. In two images, 3 phages with significantly different head and tail measurements were observed. However, different measurements are not necessarily mean that phages are different (H.-W. Ackermann, 2007). Without a morphological difference, making a conclusion just based on measurements would be misleading. TEM images revealed

phages with different morphologies co-exist in phage lysates. two phages with different morphologies were observed in phage lysate MET P1-100.

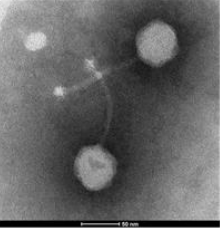

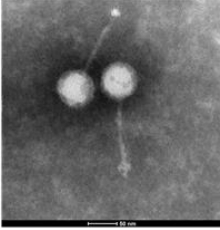

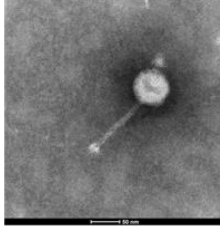

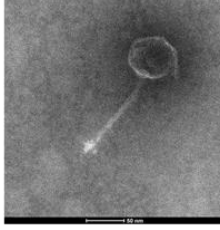

| P1-001_1 | P1-001_2 | P1-082_1 | P1-082_2 |

| Tail: 116.53±9.94 nm | Tail: 150.88±5.35 nm | Tail: 113.71±4.29 nm | Tail: 153.16±5.50 nm |

Figure 4.37 TEM analysis of phages P1-001 (left) and P1-082 (right). Two different phages were determined in both images.

Morphological differences were observed between Enteritidis phages. While 3 Enteritidis phages (P1-001, P1-082, and P1-103) had shorter tails with distinguishable base plates, P1-122 and P1-164 had considerably longer tails with an attached base plate.

| Tail: 265.53±9.41 nm | Tail: 221.07±9.55 nm | Tail: 220.66±17.46 nm | Tail: 165.66±28.24 nm |

Figure 4.39 TEM analysis of phages P1-116 (left 2), P1-164 (middle) and P1-179 (right). Two different phages were determined in P1-116, while single phage morphology was observed in P1-164 and P1-179.

Phages were attempted to be define based on Ackermann's guide (Ackermann, 2007). Principal classification of phages was carried out based on the morphological features. Beside the shape, tail and head sizes were also considered. All phages were determined as in *Caudovirales* (tailed phages) order. Majority of the phages (14/18) were assigned as a member of *Siphoviridae*, while the rest of the phages were grouped under *Myoviridae*. Typically, *Siphoviridae* has long non-contractible tail while *Myoviridae* has a contractile tail. Phages from both family had icosahedral heads (Martino et al., 2021). Classifications were determined according to ICTV Virus Taxonomy report (King et al., 2011).

| | Phage 2 | 73.11 | 4.9 | 246.36 | 12.7 | <i>Siphoviridae</i> |
| P1-116 | Phage 1 | 79.86 | 2.4 | 265.53 | 9.4 | <i>Siphoviridae</i> |
| | Phage 2 | 67.08 | 3.6 | 221.07 | 9.6 | <i>Siphoviridae</i> |
| P1-164 | Phage 1 | 60.76 | 6.6 | 220.66 | 17.5 | <i>Siphoviridae</i> |
| P1-179 | Phage 1 | 69.13 | 3.8 | 165.66 | 28.2 | <i>Siphoviridae</i> |
| P1-137 | Phage 1 | 67.70 | 3.7 | 160.96 | 14.8 | <i>Siphoviridae</i> |
| | Phage 2 | 91.57 | 8.3 | 251.07 | 12.1 | <i>Siphoviridae</i> |
| | Phage 3 | 79.31 | 4.5 | 181.55 | 6.4 | <i>Siphoviridae</i> |
| P1-100 | Phage 1 | 50.64 | 3.4 | 201.63 | 4.9 | <i>Siphoviridae</i> |
| | Phage 2 | 72.38 | 6.7 | 200.12 | 20.5 | <i>Siphoviridae</i> |
| | Phage 3 | 68.06 | 7.1 | 252.89 | 8.5 | <i>Siphoviridae</i> |

Siphoviridae are the most common family in *Caudovirales*. 61% of *Caudovirales* order belongs to *Siphoviridae*, whereas 25% of the order are grouped under *Myoviridae* (Ackermann, 2009). TEM analysis showed that almost all lysates have more than one phage. Contrarily, very similar phage plaques were observed in double plaque assay. Our results indicated that new methods should be employed to distinguish and purify the plaques.

4.11 Bacterial reduction and virulence index

Bacterial reduction experiments were done in liquid media in 96 well plates. Planktonic killing assay (PKA) were conducted in the same group of phages used in characterization by using their hosts in order to determine the kinetic relationship between the phage and the host.

Bacterial reduction curves showed the effect of phage titers on bacterial growth (Figure 4.42, Figure 4.43, Figure 4.44, Figure 4.45, Figure 4.46). Phages inhibits bacterial growth when the titer was higher than 6 log PFU/mL for at least 4 hours. After 4 to 6 hours, host developed resistance, and started to grow in all experiments (Figure 4.42). Consistently, inhibition efficacy of phages was increased with increasing titer in all experiments. Enteritidis phages inhibited bacterial growth even in low titers, (Figure 4.45, Figure 4.46). However, this was not observed for Infantis and Kentucky phages. At low levels, Infantis phages failed to inhibit bacterial growth (Figure 4.43, Figure 4.44). When phages were 8 log PFU/mL, bacterial growth was completely inhibited for hours, in all instances. Rest of the graphs were given in Appendix G. For Enteritidis phages, there was no apparent relationship with the host resistance and phage titer. The results showed that there is no linear correlation between the phage titer and host resistance. Host started to grow around same time for all titers. Since Infantis and Kentucky phages were ineffective at low titers, it might be hosts gained resistance rapidly.

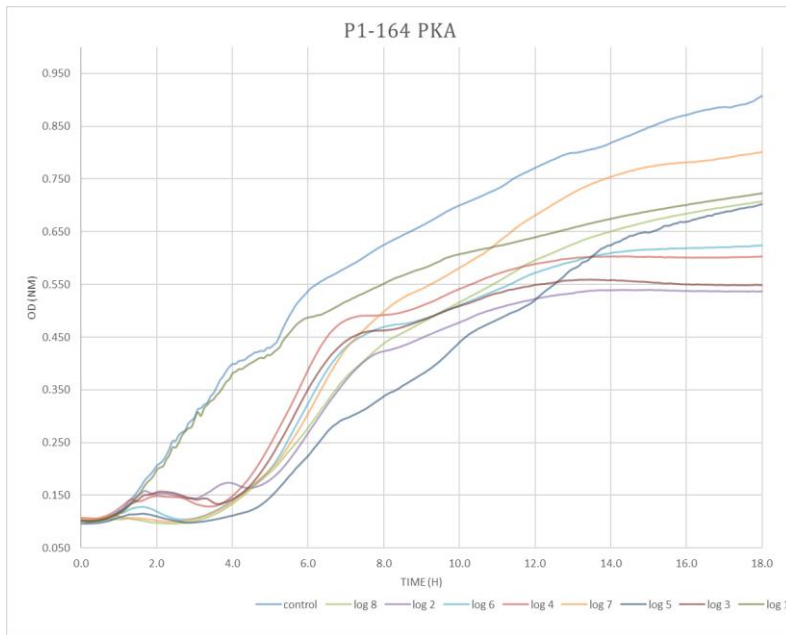

Figure 4.42 Bacterial reduction curve of P1-164 (Enteritidis). This graph shows the growth of control and phage added bacterial cultures for 18 hours.

Figure 4.43 Bacterial reduction curve of P1-0137 (Kentucky). In the graph, blue line is control (phage-free bacteria), green: 10^{-7} MOI, orange: 10^{-4} MOI, violet: 10^{-2} MOI, and red: 1 MOI

Figure 4.44 Bacterial reduction curve of P1-116 (Infantis). In the graph, red line is control (phage-free bacteria), green 10^{-7} MOI, orange: 10^{-4} MOI, violet: 10^{-2} MOI, and blue: 1 MOI

Figure 4.45 Bacterial reduction curve of P1-001 (Enteritidis). In the graph, blue line is control (phage-free bacteria), cyan: 10^{-7} MOI, violet: 10^{-6} MOI, green 10^{-4} MOI, and red: 1 MOI

Figure 4.46 Bacterial reduction curve of P1-103 (Enteritidis). In the graph, blue line is control (phage-free bacteria), green 10^{-7} MOI, orange: 10^{-4} MOI, violet: 10^{-6} MOI, and red: 1 MOI

Virulence index is the area between host growth curve and phage and host growth curve, and shows the effectiveness of phage. Area difference for all phage titers from 1 log to 8 log PFU/mL was calculated, and virulence index for each titer was found (Figure 4.47, Figure 4.48). Expectedly, virulence index was increased with the increased titer in all phages. For Enteritidis phages, P1-001, P1-103, and P1-082 had similar final virulence index results, whereas P1-122 and P1-164 were similar to each other and lower than the rest.

Figure 4.47 Virulence index score of Enteritidis phages with respect to titers

Virulence of phages is affected by a number of extrinsic and intrinsic factors. Extrinsic conditions are environmental conditions like pH, application matrix, temperature. Intrinsic conditions are phenotypic characteristics of phage such as latent period, adsorption rate and burst size (Storms et al., 2020).

For Infantis phages, a similar trend was observed. While P1-091 and P1-116 had lower virulence index than the rest of the phages, all phages showed satisfactory results at 8 log PFU/mL level.

Figure 4.48 Virulence index score of Infantis phages with respect to titers

Virulence index is a fairly new analysis to test the efficacy of phages. This experiment was introduced by Storms et al. (2020). This analysis was more reliable than spot test, as it allows phage and host grow simultaneously. In spot tests, phages might kill bacteria with lysis from without mechanism. With his mechanism, phages kill bacteria on initial contact, instead of infecting the host. In addition, it is more convenient than efficacy of plating test, which requires a lot of dilution and double plaque testing. Also, this analysis helps standardization of phage selection (Haines et al., 2021) However, it should be noted that this analysis is directly related to host. For instance, within our results, we could compare the phages affecting same hosts. Nevertheless, this analysis is particularly useful for cocktail development, as it allows the identification of phage – host combinations (Steffan et al., 2022). In their study Haines et al. (2021) compared the efficacy of plating and virulence index scores of phages. There was a direct correlation between the methods, and the authors stated that phages with a virulence

index score higher than 0.2 could be considered as efficient for a given host. In our analysis, majority of phages had V_i above 0.4 even in low levels.

4.12 Whole genome sequencing and bioinformatics

In total, 10 phages were selected for whole genome sequencing. Files of raw reads were obtained in fq format. For the bioinformatics, first, files were checked with FASTQC for read quality. All of the reads had good (>20) per base sequence quality. Adapters trimmed with TRIMMOMATIC by using default settings and quality of reads were checked once more with FASTQC. Reads had around 4.5 Mbp sequence content. Preliminary assemblies of reads were by SPAdes, and contigs were visualized with Bandage (Figure 4.49).

Figure 4.49 Bandage plot of MET P1-179 initial assembly. In the initial assembly more than 1000 contigs were produced.

However, since the coverage was too high, assemblies had very high number of contigs containing small sequences. These sequences were mostly coming from bacterial contamination (Shen & Millard, 2021). For the shorter genomes like phages it is advised to adjust coverage around 25 to 100 X (Turner, et al., 2021). Approximate coverage of reads was adjusted with the assumption that each phage genome was 100 kbp long, and coverage was calculated with the formula below;

Equation 4.1
$$Coverage = \frac{\text{number of reads} \times \text{read length}}{\text{genome size}}$$

In the equation, read length was pre-determined by the sequence technology, (Illumina NextSeq) as 150 bp, and genome size was assumed as 100 kbp, and the coverage was 100. Therefore, number of reads was adjusted to 66666 by using Seqtk toolkit. After random subsampling with Seqtk, reads were assembled again with SPAdes and visualized with Bandage. This time, a single contig with two small repeat contigs was observed (Figure 4.50).

Figure 4.50 Bandage plot of MET P1-179 assembly after subsampling. Phage genome was clearly presented in a single contig.

Contigs were examined based on their length and coverage, and optimum subsampling size was calculated accordingly for each phage genome. For example, initial assumption produced a single contig with 112 X for MET P1-179. For smaller phage genomes (e.g. 59 kbp) subsampling were adjusted to 40000 according to formula above. In most of the samples, phage genomes with acceptable coverage were assembled.

In 8 of the assemblies, more than one phage genome was observed (Table 4.8). Six of the assemblies had 2 phage genomes with acceptable coverages (25X-200X). Assemblies of MET P1-082 and MET P1-103 had 3 phages. However, for both

assembly, one of the phage contigs had lower than 25 X coverage. Those contigs were analyzed as well, but since the coverage was too low, they were considered as contamination of other phages. In two assemblies (MET P1-137 and MET P1-179) there were only one phage genome.

Presence of two phage genomes in some of the assemblies were investigated further. None of those phages produced different shaped plaque morphologies. In addition, phenotypic features such as one-step and adsorption also didn't indicate the presence of two viruses. The case of two phages might be explained with co-infection phenomenon (Diaz-Munoz, 2017). Co-infection is the simultaneous infection of two phages to same host. These phages could either be lysogenic or lytic. Co-infection is common in nature. In fact, nearly 38% of the infected bacteria contained multiple phages (Roux et al., 2015). When two phages co-infect the same host, they compete for the host resources (Chevallereau et al., 2022). In that case, only dominant phages morphology could be observed.

Assembled phage genomes were clustered according to their genome sizes. Based on the genome size, 4 different group of phages were identified. Group 1 phages were found in 8 sequences, had the highest coverage, and around 59 kbp genome size. This genome size was also observed in PFGE experiments. Group 2 phages were presented in all 5 Enteritidis sequences. These phages were around 43 kbp long, were again very similar to each other in terms of genome size. Group 3 phages were presented in three Infantis sequences, and was around (117k kbp). Group 4 had 2 phages, one Kentucky and one Infantis and had 123 kbp long genome. We also had two outlier phages (Group 5) with small coverage, one of which had more than 200 kbp genome size, and found in P1-082 which was isolated from a poultry farm in Bolu. This phage was also observed in PFGE gel pictures. The other one had 31 kbp, and found in one of the Enteritidis phages. A total of 7 phages were deposited into NCBI database. These phages were; MET P1-001_43k, P1-001_59k, P1-082_240k P1-103_31k, P1-116_117k, P1-137, and P1-179. All in all, each unique phage from our culture collection was represented. Rest of the phages will be deposited as well.

All assemblies were visualized with Bandage to check the assembly errors. Although there were small contamination sequences around 100 bp (Figure 4.50), phage contigs could be extracted by a python script. After phage genomes were cleaned from contamination, contigs were checked with Pilon for assembly errors. All assemblies were mapped with reads by using bbmap.sh tool. Resulting BAM file was sorted and indexed with Samtools (<http://www.htslib.org/doc/samtools-sort.html>). Assemblies than detected and corrected by Pilon automatically. In all assemblies, Pilon reported that confirmed bases were higher than 99.5%, and there were no corrections made.

Although assemblers produce assemblies correctly, a reordering is necessary for the phage genomes. For reorientation of genomes, all assemblies were checked by PhageTerm software. PhageTerm automatically detects the phage packaging strategy, and reorders genome accordingly. Group 1 (59 kbp), Group 3 (117 kbp), Group 4 (123 kbp) assemblies were evaluated by PhageTerm, and genomes of these phages were reoriented by the software. Packaging strategy of Group 3 and 4 phages were Direct Terminal Repeats, while Group 1 phages had clearly defined ends similar. Group 2 phages, and the outlier phages were circularly permuted with no clear, physical ends, and couldn't be evaluated by PhageTerm. PhageTerm reports were given in Appendix E. Closest relatives of these phages were identified by BLASTn. Phages were queried against Caudovirales database. Closest relatives of phages were determined, and genomes were reordered by python scripts based on the closest relative. After reordering process, all assemblies were checked for errors again by Pilon. No error was found in genome assemblies.

All phage assemblies were annotated by Prokka in two ways. First, genomes were annotated by using default settings (--genus Caudovirales --kingdom viruses). Secondly, phages were annotated by using a closely related and well defined phage genome. For this, related phages were identified by BLASTn, and complete entry of the phages were downloaded as Genbank file from NCBI database (Table 4.9).

Table 4.9 Phage information that were used as template in annotation

| Phages used | Scientific Name | Max Score | Total Score | Query Cover | Per. ident | Acc. Len |
|----------------|-----------------------------------|-----------|-------------|-------------|------------|----------|
| Group 1 | <i>Salmonella</i> virus Chi | 50752 | 82919 | 95% | 94.2 | 59578 |
| Group 2 | <i>Salmonella</i> phage celemicas | 15302 | 59526 | 90% | 92.08 | 43193 |

When the results from both methods compared, annotation by using a closely related genome as template produced a more detailed annotation (Table 4.10). In default annotation most of the coding sequences (CDS) could not be defined, and annotated as hypothetical protein, whereas in close relative annotation functional annotation of proteins were done. All annotations tables were given in Appendix F.

Annotation results revealed that phage genomes highly dense with CDS (Table 4.11). There were very small gaps between the genes. For example, 38 kbp of 43 kbp phages were annotated. Sixty-three proteins were identified with average product size 603 bp. Similarly, 28 kbp of 31 kbp phage was annotated. There were nearly no gaps between the genes. This was consistent with the literature. Phage genomes were reportedly had small gaps, even small overlaps between the genes. Furthermore, apart from some exceptions, large gaps often mean faulty annotation (Turner et al., 2021). Group 4 phages (MET P1-137 and MET P1-179) had the densest genomes. These genomes had 1.7 genes per 1 kbp on average. Both genomes had over 200 annotated proteins with 500 bp average product length.

Another feature of phage genomes is the presence of tRNA. tRNAs in phage genomes are relatively common. For example, Fong et al. (2019) reported that 36% of the sequenced *Salmonella* phages had at least one tRNA. In another study, Delesalle et al. (2016) investigated *Mycobacterium* phages and found tRNA in 41% of the genomes. In our study, only Group 1 phages lacked tRNA. Group 2 phages had 1 tRNA, and 240 k phage had 2 tRNAs. On the other hand, Group 3 phages had 24 tRNAs, whereas P-137 and P1-179 genomes had 25 and 26 tRNAs, respectively. High number of tRNAs were in agreement with literature for T5 like phages. For example, phage T5 had 24 tRNAs (J. Wang et al., 2005). There is hesitation that presence of tRNAs in the phage genomes might potentially be advantageous to host infection or replication. Therefore, phages

containing tRNAs might not be desirable in biocontrol applications (Fong et al., 2019). However, according to Bailly-Bechet et al. (2007), tRNAs increases phage virulence. In general, number of tRNAs were found in virulent phages were higher than temperate ones. tRNAs in phages allows high translation speed. Although phages rely on host cell for assembly, using their own tRNA might increase their fitness (Bailly-Bechet et al., 2007). In another view, multiple tRNAs in phage genomes might be associated with increased host range. tRNAs might be acquired by phage by recombination events involving more than one bacterial host (Delesalle et al., 2016).

Table 4.11 Basic Structural annotation results

| METUID | Host | Groups | Genome Size | CDS | tRNA | Gene Density |

Molecular taxonomy of phages was determined based on BLASTn results (Table 4.12). Phages were compared with the reference phages in NCBI database, and were considered in same genus when they share high DNA identity score (>90%) and protein identities (90%) (Moreno-Switt et al., 2015). As expected, all of the phages were in *Caudovirales* order which includes 96% of all phages (Zinke et al., 2022).

Table 4.12 Molecular Taxonomy of phages

| METUID | Host | Group | Order | Family | Subfamily | Genus |
|-----------------|-------------|--------------|-----------------------|-----------------------|-------------------------|-----------------------|
| MET P1-001_43k | Enteritidis | Group 2 | <i>Caudovirales</i> | <i>Siphoviridae</i> | <i>Guernseyvirinae</i> | <i>Jerseyvirus</i> |
| MET P1-001_59k | Enteritidis | Group 1 | <i>Caudoviricetes</i> | <i>Casjensviridae</i> | - | <i>Chivirus</i> |
| MET P1-103_31k | Enteritidis | Group 5 | <i>Caudovirales</i> | <i>Myoviridae</i> | <i>Peduovirinae</i> | <i>Peduovirus</i> |

| MET P1-091_116k | Infantis | Group 3 | <i>Caudovirales</i> | <i>Demerecviridae</i> | <i>Markadamsvirinae</i> | <i>Tequintavirus</i> |
| MET P1-179 | Infantis | Group 4 | <i>Caudovirales</i> | <i>Demerecviridae</i> | <i>Markadamsvirinae</i> | <i>Tequintavirus</i> |
| MET P1-137 | Kentucky | Group 4 | <i>Caudovirales</i> | <i>Demerecviridae</i> | <i>Markadamsvirinae</i> | <i>Epseptimavirus</i> |

Taxonomic classification further confirmed the host based differences in phages. While Enteritidis and Typhimurium phages were classified under the same subfamilies,

Infantis and Kentucky phages were grouped under same subfamilies. *Siphoviridae* are the most prevalent family of *Caudovirales*, more than half of the phage genomes in NCBI database were belong to *Siphoviridae* family. In our study, Group 1 phages were belonging to *Chivirus* genus from *Casjensviridae* family. This family was created by ICTV in 2021. *Chivirus* was previously classified under *Caudovirales* order and *Siphoviridae* family. Group 2 phages were in *Siphoviridae* family and *Jerseyvirus* genus. Both of these subfamilies were abundant in the environment, shows global presence, and targets Enteritidis and Typhimurium (Ge et al., 2022; Moreno Switt et al., 2013; Phothaworn et al., 2019, 2020). Chi like viruses are identified in 60s, and they have been reported to infect a number of genus including *Salmonella*, *Escherichia* and *Serratia* (Schade et al., 1967). The genome of Chi was sequenced in 2015 (Hendrix et al., 2015). Phage Chi is a flagellotropic phage. Infection starts with binding of phage to flagellar filament, and uses rotation of flagella to reach to cell (Esteves et al., 2021). In addition, two outlier phages from Group 5 were belong to *Myoviridae* family. One the outlier phages (31 kbp) were belong to *Peduvirinae* subfamily, and classified as P2 like virus due to close genomic relatedness. Coliphage P2 is a temperate phage that has been identified in *Escherichia*, *Pseudomonas*, and *Salmonella* (Moreno-Switt et al., 2015). 240 kbp phage was a jumbophage (>200 kbp). Jumbophages are so rare that Yuan and Gao reported less than 100 jumbophages were managed to isolated and classified by 2016 (Yuan & Gao, 2017). Although the number of known jumbo phages has been increased in the last 5 years, they are still very rare compared to other phages. Closest relative of the jumbophage was sequenced by (Lee et al., 2011). Genomic features of that jumbophage (SPN3US) were very similar to ours. It had a genome around 240 kbp with a %48,5 GC content, had two tRNAs and had similar gene density.

Group 3 and 4 phages were identified as *Demerecviridae*. *Demerecviridae* was appointed as a new family by International Committee on Taxonomy of Viruses (ICTV) (Adriaenssens et al., 2020). The members of this family were formerly belong to *Siphoviridae* (Turner et al., 2021). Three subfamilies were presented in this family, including *Markadamsvirinae*. The most well-known phage of this group is coliphage T5. T5 has a very similar genomic features to Group 3 and 4 phages. It has 121kb

genome, 24 tRNAs and 39.3% GC content (Adriaenssens et al., 2020). Similar to our phages, T5 has long DTR.

Taxonomy of our phages were also investigated by using Genetic Relationship Applied to Virus Taxonomy (GRAViTy) tool (Turner et al., 2021). A dendrogram that contains all dsDNA prokaryotic viruses plus our phages was created (Figure 4.51). In addition, another dendrogram, built by orthologous genes of lytic *Salmonella* phages were visualized to see the distribution of our phages (Figure 4.52). Phylogenetic relationship of our phages were given in Appendix G.

Figure 4.51 Dendrogram of all dsDNA bacterial viruses. Dendrogram generated by Gravity, and visualized using ITOL.

Figure 4.52 Neighbor joining tree based on orthologues genes of lytic *Salmonella* phages. Adapted from (Moreno-Switt et al., 2015).

Horizontal gene transfer is one of the major drivers of bacterial evolution. Bacteria may acquire genetic materials from environment, other prokaryotes, and even eukaryotes. Transduction is a horizontal gene transfer mechanism, in which genetic material is acquired by bacteria through phage infection (Soucy et al., 2015). Brown-Jaque et al. (2015) stated that up to 20% of bacterial phage has viral origins, which shows the effect of transduction on bacterial evolution. Transduction is also a significant mechanism in the recent spread of antibiotic resistance genes (Hassan et al., 2021). Recent studies showed that *Salmonella* might acquire resistance genes via transduction (Bearson & Brunelle, 2015; Gabashvili et al., 2020). These studies showed the importance of phage genome analysis before biocontrol applications. Therefore, all phages were screened for the presence of AR genes with ResFinder database. None of the phages had AR genes.

In addition to resistance, virulence genes might also be transferred by transduction (Kondo et al., 2020). A striking example was the outbreak strain of *E. coli* O104:H4 which caused more than 3800 cases across the EU. That strain gained stx2a Shiga-toxin encoding gene via transduction (Beutin & Martin, 2012). Similar to antibiotic genes,

virulence factors genes had to be screened. Virulence genes were screened by BLAST. Virulence Factors of Pathogenic Bacteria (VFDB) database was downloaded to our local computer, and genes were queried in BLAST against the phages. There was no virulence gene in our phages. However, there were a number of hypothetical proteins with unknown function in phage annotations. As a result, these hypothetical genes should be evaluated to ensure they are not harmful (Ge et al., 2022).

Lysogenic phages are significantly more associated with transduction compared to lytic phages (L.-C. Fortier & Sekulovic, 2013). For example, a monophasic *S. Typhimurium* strain that is associated with an epidemic had acquired virulence gene *sopE* from a lysogenic phage (Tassinari et al., 2020). As a result, lysogenic phages cannot be used in pathogen biocontrol. Therefore, integrase gene, which is found in temperate phages, was screened in phages. Group 5 31 kbp phage had 2 integrase genes. That phage was most probably existed in host Enteritidis strain (MET S1-001) as a prophage, and contaminated phage solution (MET P1-103) during analyses. The results show that P1-103 couldn't be used before it is completely cleared from contamination. Moreover, the results also indicated the importance of using fully characterized host in phage studies.

4.13 *In vitro* phage application on feed

Efficacy of phages MET P1-001, P1-137, P1-179, and P1-100 were tested on *Salmonella* contaminated feed (Figure 4.54, Figure 4.53, Figure 4.55, Figure 4.56). These phages selected because they had the higher virulence index at 8 log PFU/mL. Each experiment was done separately, and compared to their controls only.

Figure 4.53 *Salmonella* Enteritidis counts on treated and untreated feed samples. Two different initial concentrations; 10³ (left) and 10⁶ (right) were tested.

Figure 4.54 *Salmonella* Infantis counts on treated with MET P1-179 and untreated feed samples. Two different initial concentrations; 10³ (left) and 10⁶ (right) were tested.

Figure 4.55 *Salmonella* Infantis counts on treated with MET P1-100 and untreated feed samples. Two different initial concentrations; 10³ (left) and 10⁶ (right) were tested.

Figure 4.56 *Salmonella* *Infantis* counts on treated with MET P1-179 and untreated feed samples. Two different initial concentrations; 10^3 (left) and 10^6 (right) were tested.

There was a significant difference between the efficacy of Enteritidis phage and *Infantis* phages. For *Infantis*, none of the tested 3 phages exhibited a satisfactory reduction. While significant changes were observed at some data points, they were found inconclusive and unreliable. On the other hand, P1-001 caused huge reductions in Enteritidis populations on feed. At MOI 10^5 , P1-001 reduced the Enteritidis populations to undetectable levels after 6 hours of incubation. At MOI 10^2 , 1.3 log reduction was observed in Enteritidis population after 6 hours. Both of the reductions were significant ($p < 0.05$).

Table 4.13 Phage application results at 2 and 6-hour incubation for different phages

| Phage | <i>Salmonella</i> initial dose (log CFU/mL) | Incubation time (h) | Treated | Untreated |
|------------|---|---------------------|-------------------------|-------------------------|
| MET P1-179 | 3.409771968 | 2 | 2.38907563 ^a | 2.80103 ^a |
| | | 6 | 4.61610897 ^a | 4.60953 ^a |

| | | 6 | 3.29327745 ^b | 3.531479 ^a |
| | 6.041392685 | 2 | 6.56951592 ^a | 6.590922 ^a |
| | | 6 | 7.3104734 ^a | 7.401113 ^a |
| MET P1-001 | 3.43461586 | 2 | 3.16111 ^a | 0.33333333 ^b |
| | | 6 | 4.267647 ^a | 0 ^b |
| | 6.428666248 | 2 | 5.889076 ^a | 5.10034333 ^b |
| | | 6 | 7.040625 ^a | 5.69968006 ^b |

These results were in agreement with phenotypic characteristics such as latent period and burst size and adsorption. P1-001 had shorter latent period, higher burst size and better adsorption rates than the rest of tested phages. On the other hand, these results contradicted with planktonic killing assay. In that experiment, P1-100, P1-137, and P1-179 were found to have higher virulence index than P1-001 at 8 log PFU/mL level. The difference between these experiments might be associated with the difference in matrix. Feed is much more complex environment than media, and it might have affected the performance of phages and bacteria.

Limited number of reports are available in the literature concerning the in vitro application of phages in feed. Andreatti Filho et al. (2007) treated *Salmonella* Enteritidis contaminated feed with a monophage at different titers. In that study, two initial Enteritidis concentration (10^3 and 10^6 CFU/mL) were used. Feed were incubated for 6 hours after the application of phage at 8 log PFU/mL. *Salmonella* counts in phage treated feeds were 1.3 log CFU/mL lower than the untreated control for 10^3 initial dose. For, 10^6 initial dose, the reduction after incubation was only 0.4 log CFU/mL, and was not found significant (Andreatti Filho et al., 2007).

In another study, a phage cocktail was applied in vitro to reduce *Salmonella* Enteritidis population in feed (Wójcik et al., 2020). In that study, 10^7 PFU/mL phage cocktail was applied in two ways, spray and immersion, to feed contaminated with 10^3 CFU/mL *Salmonella* Enteritidis. After 6 hours of incubation, *Salmonella* counts of treated and untreated feed were compared. At room temperature, phage cocktail caused 0.7 log reduction, whereas at 37 °C the reduction was increased to 1 log. There was no difference between the application methods. The phage cocktail in that study was consisting of 4 phages (Wójcik et al., 2020). Interestingly, all of the phages were from same genus with our phages (Tequintavirus and Jerseyvirus). In fact, our Enteritidis phages is a member of Jerseyvirus genus as well.

CHAPTER 5

CONCLUSION

Salmonella contamination may occur throughout the food chain. Biocontrol of *Salmonella* from pre-harvest to retail level is essential for food safety. For each step, different actions may be used such as heat treatment, antibiotics, and surface decontaminants. However, each treatment comes with a cost. Misuse and overuse of antibiotics in medicine and veterinary caused a serious “superbug” problem which cannot be treated by first line of antibiotics. Furthermore, *Salmonella* serotypes show variation between regions and products.

Phages offer an alternative food safety method which can be used in different steps of food production steps. Phages have a number benefits compared to traditional biocontrol methods. However, certain requirements must be met before the utilization of phages. These requirements include the genomic and phenotypic features of phages as well as their interaction with target organism.

In this study, 12 *Salmonella* strains and 68 *Salmonella* phages were isolated from different regions in Turkey. *Salmonella* positive samples were higher than the EU average. Serotypes of 9 *Salmonella* isolates were also determined by PFGE. 5 of the isolates were either belonged to Kentucky or Infantis serotypes. Genomic characterization showed that isolates showed serotype based clustering. Antibiotic resistance profiles of the isolates were determined. 66% of the isolates were multi drug resistant. In addition, plasmid mediated fluoroquinolone genes were found in one isolate, which confers resistance against a clinically important antibiotic, ciprofloxacin.

46 Enteritidis, 27 Typhimurium, 11 Infantis, 3 Kentucky, 3 Hadar, 2 Anatum, 2 Telaviv, and 1 Montevideo phage was isolated from poultry and cattle farms as well as wastewater facility in 11-month span. All phages were purified and stored in triplicate. Each phage was tested against 36 hosts from 18 serotype to determine their lysis profile.

Majority of the phages show a board host range (>10 host). In general, Typhimurium and Enteritidis strains were infected by same phages, were as those phages were ineffective against Infantis. Some *Salmonella* strains (i.e. Hadar, Braenderup, Mbandaka, Liverpool) were highly resistant against phages. Phages and hosts were clustered based on the interactions. Based on their host interactions, 5 Enteritidis-Typhimurium, 4 Infantis, and 1 Kentucky phage were selected for further characterization.

Phenotypic characterization of selected phages was done. MET P1-001 (Enteritidis) had the shortest latent period and highest burst size among the phages. Anatum phage had the second best burst size-latent period combination. Infantis phages had lower burst size and longer latent period than other phages. Similar results were observed in adsorption rates. Infantis phages had the worst free phage % after 10-minute adsorption whereas Hadar phage was the best.

Phage genome sizes were determined with PFGE. 19 phages produced bands between 30 kbp to 240 kbp. In some samples, two bands were observed. These bands might be resulted due to contamination of another phage. Morphology of the phages was investigated by TEM. Different measurements and different morphologies were observed in phage lysates. Majority of the phages showed *Siphoviridae* morphology while a number of phages were *Myoviridae* like morphology.

Whole genome sequencing is the current gold standard for characterization of phages. Genomes of 10 phages were sequenced. In 8 samples, multiple phage genomes were present. However, these phages couldn't be differentiated by plaque morphology. All genomes were assembled and annotated. Also taxonomy of genomes was determined in molecular level. In all Enteritidis phages, there were one Chivirus-like and one Jerseyvirus-like genome. In addition, in P1-103 there was a prophage resembling Coliphage P2. Furthermore, in P1-082 there was a jumbophage with 240 kbp genome. In 3 Infantis phages there were a Chi-like virus and a T5 like virus genome. Two samples had monophage genomes. Genome sizes of phages were in agreement with PFGE. None of the phage genomes carried a virulence or antibiotic resistance gene.

Dynamic relationship between the phage and host were investigated with bacterial reduction curve. Enteritidis phages were successfully inhibited bacterial growth for 4 to 6 hours even in low concentrations. Similar effect observed in Infantis phages only at high titers. Virulence index of phages were determined based on their reduction curve. Among Enteritidis phages P1-082 had the highest virulence index at 8 log PFU/mL level whereas 164 had the lowest. On the other hand, P1-137 had the highest virulence index among all tested phages. All phages were found effective against their host.

Several phages were tested against their hosts in feed matrix. 10^3 and 10^6 CFU/ mL *Salmonella* Enteritidis and Infantis were inoculated into separate, sterile feeds, and incubated 6 hours after 8 log PFU/ mL phage application. P1-001 reduced Enteritidis populations significantly at both contamination levels. However, Infantis phages were ineffective. The results might be explained with the poor latent period and burst size combination of Infantis phages.

All in all, our study documented a wide range of phages and their interaction with different *Salmonella* strains. Furthermore, phenotypical and genomic features of a number of phages were documented. Some of those phages have already been utilized in different commercial phage cocktails. In this study, we identify and characterize phages with commercialization potential.

Further characterization of phages is required before commercialization. Their efficacy in different food matrices or food contact surfaces should be tested. In addition, preparation of a cocktail consisting of these phages would be necessary to increase the host range.

G. Phylogenomic distance tree

Dendrogram showing the phylogenetic relationship between the phages. Numbers on branches indicate the bootstrap values. Tree was drawn with VICTOR.

H. Bacterial reduction curves

Bacterial Reduction curve of MET P1-001 against Enteritidis

Bacterial Reduction curve of MET P1-103 against Enteritidis

Bacterial Reduction curve of MET P1-164 against Enteritidis

Bacterial Reduction curve of MET P1-082 against Enteritidis

Bacterial Reduction curve of MET P1-116 against Infantis

Bacterial Reduction curve of MET P1-091 against *Infantis*

Bacterial Reduction curve of MET P1-100 against Infantis

Bacterial Reduction curve of MET P1-179 against Infantis

Bacterial Reduction curve of MET P1-137 against *Infantis*

i. PFGE gel pictures

PFGE gel picture of phages. From left to right: MET S1-713 (ref), MET P1-001-A, MET P1-001-B, MET P1-001-C, MET P1-100, MET P1-137, MET S1-713 (ref)

PFGE gel picture of phages. From left to right: MET S1-713 (ref), MET P1-049, MET P1-001-B, MET P1-001-C, MET P1-100, MET P1-137, MET S1-713 (ref)

J. Chemicals and materials used in this study

| Chemicals | Producers |
|--|-----------------------------------|
| American Bacteriological Agar | Condalab (Madrid, Spain) |
| Luria Bertani (LB) Broth | Condalab (Madrid, Spain) |
| Buffered Peptone Water | Merck (Darmstadt, Germany) |
| Xylose-Lysin-Desoxycholat (XLD) Agar | Merck (Darmstadt, Germany) |
| Rappaport-Vassiliadis <i>Salmonella</i> Enrichment Broth | Merck (Darmstadt, Germany) |
| Brain Heart Infusion Broth | Merck (Darmstadt, Germany) |
| Gelatin from bovine skin | Merck (Darmstadt, Germany) |
| Sodium chloride | Merck (Darmstadt, Germany) |
| Magnesium sulfate hexahydrate (MgSO ₄ *6H ₂ O) | Merck (Darmstadt, Germany) |
| Ethylenediaminetetraacetic acid | Merck (Darmstadt, Germany) |
| TRIS hydrochloride | Merck (Darmstadt, Germany) |
| SeaKem Gold Agarose | Lonza (USA) |
| Boric Acid | Merck (Darmstadt, Germany) |
| Proteinase K | Roche |
| XbaI | Roche |
| H buffer | Roche |
| DirectLoad PCR 100 bp Low Ladder | Sigma-Aldrich (St. Lois, MO, USA) |
| 0.45 µm and 0.22 µm poresize syringe filters | ISOLAB |
| Ammonium acetate | Merck (Darmstadt, Germany) |
| Phosphotungstic Acid | Merck (Darmstadt, Germany) |

CURRICULUM VITAE

Mustafa GÜZEL

Research Assistant

Department of Food Engineering

Hitit University

19030, Çorum, TURKEY

+90(364)227-4533

mustafaguzel@hitit.edu.tr

musguzel@gmail.com

GENERAL INFORMATION

Academic Experience

| Degree Received | Institution | Date |
|------------------------|--|------|
| Ph.D. Food Engineering | Middle East Technical University | 2022 |
| | Thesis Title: An Alternative Way for Reduction of Pathogens in Poultry Farms: Bacteriophages Against Antimicrobials | |
| M.S. Food Engineering | Texas A&M University | 2015 |
| | Thesis Title: Quantitative Microbial Risk Assessment for <i>Listeria monocytogenes</i> in | |

Fresh-cut Cantaloupe and Fresh-cut
Romaine Lettuce

B.S. Food Engineering Ankara University 2008

Professional Experience

| Position | Department | Institution | Dates |
|--------------------|------------------|---------------------|-------|
| Teaching Assistant | Food Engineering | Hitit University | 2015- |

Membership in Professional Societies

2015 – 2017 Institute of Food Technologists (IFT)

2018 - Turkish Society of Microbiology

Awards and Fellowships

Ministry of National Education, Selection and Placement of Candidates Sent
Abroad for Postgraduate Education. Master's education, 2011-2015

Visiting Scholar, University of Illinois, Department of Food Science, Genomic
Characterization of *Salmonella* Isolates from Poultry in Querétaro, 2015-2018,
01/02/2019-30/04/2019

Short Term Scientific Mission Grant, COST Action 16110, Aarhus University,
Department of Environmental Science, Research, 20/01/2020 - 07/02/2020

Congress Attendance Grant, FEMS 2022, Belgrade, 30/06/2022 – 03/07/2022
